received 23th April 1998, revised 23th November 1998, accepted 27th January 1999.

We prove the existence of an invariant ring $\mathbb{C}[X_1,\ldots,X_n]^{\Gamma}$ generated by elements with a total degree of at most 2, which has no finite SAGBI basis with respect to any admissible order. Therefore, 2 is the optimal lower bound for the total degree of generators of invariant rings with such a property.

Keywords: SAGBI basis, Invariant ring, Analysis of algorithms.

In [2], the structure of SAGBI (Subalgebra Analogue to Gröbner Basis for Ideals [5]) bases for invariant rings of permutation groups with respect to the lexicographical order $<_{lex}$ with $X_1>_{lex}\ldots>_{lex}X_n$ was investigated. It turned out that only invariant rings of direct products of symmetric groups have a finite SAGBI basis, which is then, in addition, multilinear. Of course, it would be of interest to have such a strong characterization with respect to any other admissible order [4, 6]. To achieve this seems to be all but trivial. One step towards the understanding of the behavior of SAGBI bases for invariant rings with respect to any admissible order is the investigation of important special cases. Recently, the non-finiteness of SAGBI bases for $\mathbb{C}[X_1,X_2,X_3]^{\langle(123)\rangle}$ with respect to any admissible order was proven in [3]. In addition, it was shown that with respect to the number of variables, $\mathbb{C}[X_1,X_2,X_3]^{\langle(123)\rangle}$ is the "smallest" unique example for such a ring of polynomial invariants of a permutation group.

In this note, we show the existence of an invariant ring generated only by polynomial invariants with a total degree of at most 2, which has no finite SAGBI basis with respect to any admissible order. Hence, 2 is the optimal lower bound, because any invariant ring generated by polynomial invariants with a total degree of at most 1 has for trivial reasons a finite SAGBI basis. In addition, we can show that our example has with respect to this property the minimal number of variables 4, if we restrict ourself to polynomial invariants of permutation groups, and the minimal group order 2.

We briefly recall our notation, and then state and prove our result.

66 Manfred Göbel

- The natural and complex numbers are denoted by \mathbb{N} and \mathbb{C} ,
- $K[X_1,\ldots,X_n]$ is the commutative polynomial ring over K in the indeterminates X_1,\ldots,X_n ,
- T is the set of terms (= power-products of the X_i) in $K[X_1, \ldots, X_n]$,
- GL(K, n) denotes the general linear group over K,
- G < GL(K, n) a permutation group,
- and S_n the symmetric group of n symbols.

A polynomial $f \in K[X_1, ..., X_n]$ is called Γ -invariant, if

$$f = \pi(f) := f(\sum_{i=1}^{n} a_{1i}X_i, \dots, \sum_{i=1}^{n} a_{ni}X_i) \quad \forall \pi = (a_{ij})_{1 \le i, j \le n} \in \Gamma < GL(K, n).$$
 (1)

The ring $K[X_1,\ldots,X_n]^{\Gamma}$ denotes the K-algebra of Γ -invariant polynomials in $K[X_1,\ldots,X_n]$, and

$$orbit_{\Gamma}(f) = \sum_{p \in \{\pi(f) \mid \pi \in \Gamma\}} p \tag{2}$$

the Γ -invariant orbit of f. An admissible order < on the set of terms T is such that

$$t > 1 \ \forall 1 \neq t \in T \ \text{and} \ st_1 > st_2 \ \forall s, t_1, t_2 \in T \ \text{with} \ t_1 > t_2 \ [4, 6].$$
 (3)

HT(f) is the leading term of $f \in K[X_1, \dots, X_n]$ with respect to a given admissible order <, and HC(f) denotes its coefficient. A term $t = X_1^{e_1} \dots X_n^{e_n}$ is called multilinear iff $\{e_1, \dots, e_n\} \subseteq \{0, 1\}$.

Lemma 1 Let $G = \langle (12)(34) \rangle$. Then $\mathbb{C}[X_1, X_2, X_3, X_4]^G$ is generated by

$$B = \{ X_1 + X_2, X_1 X_2, X_3 + X_4, X_3 X_4, X_1 X_4 + X_2 X_3 \}.$$
 (4)

Proof A close look at the G-invariant orbits of $\mathbb{C}[X_1, X_2, X_3, X_4]^G$ via the reduction technique described in [1] shows that we only have to find a representation of $orbit_G(X_1^2X_3)$, $orbit_G(X_1X_3^2)$, $orbit_G(X_1^2X_4)$, and $orbit_G(X_1X_4^2)$ in terms of the elements of B. We have

$$\begin{aligned} orbit_G(X_1^2X_3) &= (X_1+X_2)(X_1X_3+X_2X_4) - (X_1X_2)(X_3+X_4), \\ orbit_G(X_1X_3^2) &= (X_3+X_4)(X_1X_3+X_2X_4) - (X_3X_4)(X_1+X_2), \\ orbit_G(X_1^2X_4) &= (X_1+X_2)(X_1X_4+X_2X_3) - (X_1X_2)(X_3+X_4), \text{ and} \\ orbit_G(X_1X_4^2) &= (X_3+X_4)(X_1X_3+X_2X_4) - (X_3X_4)(X_1+X_2), \\ &\text{with} \\ X_1X_3+X_2X_4 &= (X_1+X_2)(X_3+X_4) - (X_1X_4-X_2X_3). \end{aligned}$$

For any other non-multilinear special $orbit_G(X_1^{e_1}X_2^{e_2}X_3^{e_3}X_4^{e_4})$ not listed so far, we have $e_1, e_2 > 0$ or $e_3, e_4 > 0$, i.e. we can rewrite these orbits as

$$(X_1X_2)orbit_G(X_1^{e_1-1}X_2^{e_2-1}X_3^{e_3}X_4^{e_4})$$
(5)

or

$$(X_3X_4)orbit_G(X_1^{e_1}X_2^{e_2}X_3^{e_3-1}X_4^{e_4-1}).$$
 (6)

This completes the proof of the lemma. \Box

Lemma 2 Let $G = \langle (12)(34) \rangle$. Then $\mathbb{C}[X_1, \ldots, X_n]^G$ has no finite SAGBI basis with respect to \leq_{lex} .

Proof The permutation group G is not a direct product of symmetric groups. So, following [2], $\mathbb{C}[X_1, X_2, X_3, X_4]^G$ can not have a finite SAGBI basis with respect to $<_{lex}$. \square

Theorem 3 Let $G = \langle (12)(34) \rangle$. Then $\mathbb{C}[X_1, X_2, X_3, X_4]^G$ has no finite SAGBI basis with respect to any admissible order <.

Proof Assume that $\mathbb{C}[X_1,X_2,X_3,X_4]^G$ has a finite SAGBI basis B with respect to <, and assume further w.l.o.g. that $X_1 > X_2, X_3 > X_4$, and $X_1 > X_3$. Then we have either $X_2 > X_3$, or $X_3 > X_2$. And further, the basis B contains the multilinear G-invariant orbits

$$\{X_1 + X_2, X_1X_2, X_1X_4 + X_2X_3, X_3 + X_4, X_3X_4\}$$
 (7)

and a finite number of non-multilinear G-invariant orbits of the form

$$\psi_{e_1,e_2} = X_1^{e_1} X_4^{e_2} + X_2^{e_1} X_3^{e_2} \tag{8}$$

with $e_1 \neq e_2 \geq 1$. Note that the leading term of $\psi = X_1X_4 + X_2X_3$ is with respect to < not determined so far. Our goal is now to construct an infinite sequence of leading terms t_0, t_1, t_2, \ldots of G-invariant orbits such that almost all of these terms are not generated by products of leading terms of the polynomials in B. Let

$$t_0 = \begin{cases} HT(orbit_G(X_1X_4^2)), \text{if } HT(\psi) = X_1X_4\\ HT(orbit_G(X_2^2X_3)), \text{otherwise,} \end{cases}$$

and let $s_0 = X_4$, if $t_0 = X_1 X_4^2$, $s_0 = X_2 X_3$, if $t_0 = X_2 X_3^2$, $s_0 = X_2$, if $t_0 = X_2^2 X_3$, and $s_0 = X_1 X_4$ otherwise. Furthermore, for $i \ge 1$, define $t_i = HT(orbit_G(t_{i-1}s_{i-1}))$, and let $s_i = s_{i-1}$, if $t_i = t_{i-1}s_{i-1}$, and let

$$s_i = \begin{cases} X_1^{e_1} X_4^{e_2}, & \text{if } t_{i-1} = X_2^{e_1} X_3^{e_2} \\ X_2^{e_1} X_3^{e_2}, & \text{otherwise.} \end{cases}$$

For all $i \in \mathbb{N}$, we have t_i is $X_1^{e_1}X_4^{e_2}$ or $X_2^{e_1}X_3^{e_2}$ with $1 \le e_1 < e_2$, if $HT(\psi) = X_1X_4$, and with $e_1 > e_2 \ge 1$, otherwise (see Figure 1 on the following page for an example sequence). The total degree of t_{i_1} is always smaller than the total degree of t_{i_2} for $i_1 < i_2 \in \mathbb{N}$, and s_i is never a leading term of a G-invariant orbit for all $i \in \mathbb{N}$.

Our selection of the s_i , $i \in \mathbb{N}$ ensures that the sequence of leading terms t_0, t_1, t_2, \ldots in $\mathbb{C}[X_1, X_2, X_3, X_4]^G$ has by construction the following properties: First, t_i is never a product of terms in

$$W_{i-1} = \{X_1, X_1 X_2, HT(\psi), X_3, X_3 X_4\} \cup \{t_0, \dots, t_{i-1}\} \quad \forall i \in \mathbb{N}.$$
(9)

Each product of terms in W_{i-1} matching the exponent of X_4 (X_3) is unable to match simultaneously the exponent of X_1 (X_2), if $t_i = X_1^{e_1} X_4^{e_2}$ ($X_2^{e_1} X_3^{e_2}$). Second, all other leading terms in $\mathbb{C}[X_1, X_2, X_3, X_4]^G$ have an expression as a product of terms in $W = \{X_1, X_1 X_2, HT(\psi), X_3, X_3 X_4\} \cup \{t_0, t_1, t_2, \ldots\}$.

68 Manfred Göbel

Altogether, this implies that any t_i with a sufficiently large total degree has no expression as a product of leading terms of the polynomials in the finite set B. Hence, there exists no finite SAGBI basis of $\mathbb{C}[X_1, X_2, X_3, X_4]^G$ with respect to < (contradiction). \square

Figure 1 illustrates the way of the sequence $t_0,\,t_1,\,t_2,\ldots$ thru the terms in question with respect to a given admissible order <. The upper (lower) half of the figure shows the first couple of $X_1^{e_1}X_4^{e_2}$ ($X_2^{e_1}X_3^{e_2}$) terms denoted by $e_1..e_2$ (e_1e_2 .) with $0< e_1< e_2$. We can see in this example that $t_0=X_1X_4^2$ ($s_0=X_4$), $t_1=X_2X_3^3$ ($s_1=X_2X_3^2$), $t_2=X_2^2X_3^5$ ($s_2=X_2X_3^2$), $t_3=X_1^3X_4^7$ ($s_3=X_1^2X_4^5$), $t_4=X_1^5X_4^{12}$ ($s_4=X_1^2X_4^5$), and so on. The set $W=\{X_1,X_1X_2,X_1X_4,X_3,X_3X_4\}\cup\{t_0,t_1,t_2,\ldots\}$

                                                                             .10 14.
```

Fig. 1: The leading term pattern for a given admissible order <.

separates the terms in the set $\{X_1^{e_1}X_4^{e_2}, X_2^{e_1}X_3^{e_2} \mid 0 < e_1 < e_2\}$ into leading terms (font: times-bold) and other terms (font: times-roman) such that either $X_1^{e_1}X_4^{e_2}$ or $X_2^{e_1}X_3^{e_2}$ is a leading term, and such that any other leading term in $\mathbb{C}[X_1, X_2, X_3, X_4]^G$ is a product of terms in W.

The invariant ring $\mathbb{C}[X_1,\ldots,X_n]^\Gamma$ is generated by polynomials with a total degree of at most 1 implies that Γ is the trivial group, and that the generators are X_1,\ldots,X_n . Hence, 2 is the smallest possible and therefore optimal lower bound for the generators of an invariant ring without a finite SAGBI with respect to any admissible order. Furthermore, we must have $|\Gamma| \geq 2$ for any $\mathbb{C}[X_1,\ldots,X_n]^\Gamma$ with this property, i.e. our example is minimal with respect to the group order, because |G| = 2.

Lemma 4 Let n < 4, and let $\mathbb{C}[X_1, \dots, X_n]^G$ be generated by elements with a total degree of at most 2. Then $\mathbb{C}[X_1, \dots, X_n]^G$ has a finite SAGBI basis.

Proof G is either $S_1, S_1 \times S_1, S_2, S_1 \times S_2, S_2 \times S_1$, or $S_1 \times S_1 \times S_1$, i.e. $\mathbb{C}[X_1, \dots, X_n]^G$ has a finite SAGBI basis (Cf. [2]). \square

Hence, $\mathbb{C}[X_1, X_2, X_3, X_4]^G$ with $G = \langle (12)(34) \rangle$ is, in addition, minimal with respect to the number of variables, if we restrict ourself to polynomial invariants of permutation groups. Note that these results hold not only for the field \mathbb{C} but for any ring R, because our arguments are based on G-invariant orbits.
