

60/102 Null Boundary Cellular Automata based expander graphs

Sung-Jin Cho^{1†}Un-Sook Choi²Han-Doo Kim³Yoon-Hee Hwang¹Jin-Gyoung Kim¹¹*Department of Applied Mathematics, Pukyong National University, Busan 608-737, Korea*²*Department of Media Engineering, Tongmyong University, Busan 626-847, Korea*³*School of Computer Aided Science, Institute of Basic Science, Inje University, KimHae 621-749, Korea*

Expander graphs are useful in the design and analysis of communication networks. Mukhopadhyay et al. introduced a method to generate a family of expander graphs based on nongroup two predecessor single attractor Cellular Automata(CA). In this paper we propose a method to generate a family of expander graphs based on 60/102 Null Boundary CA(NBCA) which is a group CA. The spectral gap generated by our method is maximal. Moreover, the spectral gap is larger than that of Mukhopadhyay et al.

Keywords: Expander graphs, 60/102 NBCA, Spectral gaps, Bipartite graphs, Eigenvalue.

1 Introduction

Expander graphs were first defined by Bassalygo and Pinsker and their existence first proved by Pinsker in the early 1970s [10]. Also expander graphs have utility in computational settings such as in the theory of error correcting codes and the theory of pseudorandomness as well as a tool for proving results in number theory and computational complexity [6, 8, 11]. Expander graphs are useful in the design and analysis of communication networks. Mukhopadhyay et al. introduced a method to generate a family of expander graphs based on nongroup two predecessor single attractor Cellular Automata(CA). In this paper we propose a method to generate a family of expander graphs based on 60/102 Null Boundary CA(NBCA) which is a group CA. The merit of our method is that it use regular, modular and cascable structure of 60/102 NBCA [1, 3, 4] to generate regular graphs of good expansion property with less storage. The spectral gap generated by our method is maximal. Moreover, the spectral gap is larger than that of Mukhopadhyay et al. [9].

2 Preliminaries

CA consist of a number of interconnected cells arranged spatially in a regular manner, where the state transition of each cell depends on the states of its neighbors. The CA structure investigated by Wolfram

[†]This work was supported by the Pukyong University Research Fund in 2009(PK-2009-26).

[12] can be viewed as a discrete lattice of sites (cells), where each cell can assume the value either 0 or 1. The next-state of a cell is assumed to depend on itself and on its two neighbors (3-neighborhood dependency). If the next-state function of a cell is expressed in the form of a truth table, then the decimal equivalent of the output is conventionally called the rule number for the cell.

Neighborhood state	111	110	101	100	011	010	001	000	
Next state	0	0	1	1	1	1	0	0	rule 60
Next state	0	1	1	0	0	1	1	0	rule 102

The top row gives all eight possible states of the three neighboring cells (the left neighbor of the i th cell, the i th cell itself, and its right neighbor) at the time of instant t . The second and third rows give the corresponding states of the i th cell at the time of instant $t + 1$ for two illustrative CA rules.

Informally, expander graph is a graph $G = (V, E)$ in which every subset S of vertices *expands* quickly, in the sense that it is connected to many vertices in the set \bar{S} of complementary vertices.

Definition 2.1 ([8]). Suppose $G = (V, E)$ has n vertices. For a subset S of V define the *edge boundary* of S , ∂S , to be the set of edges connecting S to its complement \bar{S} . That is, ∂S consists of all those edges (v, w) such that $v \in S$ and $w \notin S$. The *expansion parameter* for G is defined by

$$h(G) \equiv \min_{S: |S| \leq n/2} \frac{|\partial S|}{|S|}$$

where $|X|$ denotes the size of a set X .

Example 2.2. Suppose G is the complete graph with n vertices, i.e., the graph in which every vertex is connected to every other vertex. Then for any vertex in S , each vertex in \bar{S} is connected to all the vertices in \bar{S} , and thus $|\partial S| = |S| \times |\bar{S}| = |S|(n - |S|)$. It follows that the expansion parameter for G is given by

$$h(G) \equiv \min_{S: |S| \leq n/2} (n - |S|) = \lceil \frac{n}{2} \rceil$$

It is a marvellous fact that properties of the *eigenvalue spectrum* of the adjacency matrix $A(G)$ can be used to understand properties of the graph G . This occurs so frequently that we refer to the spectrum of $A(G)$ as *the spectrum of the graph G* . It is useful because the eigenvalue spectrum can be computed quickly, and certain properties, such as the largest and smallest eigenvalue, the determinant and trace, can be computed extremely quickly [8].

Let $G = (V, E)$ be an undirected graph and $A(G)$ be the adjacency matrix of the graph G . And let $\lambda_i(A(G)) (1 \leq i \leq n)$ be eigenvalues of $A(G)$. Then $A(G)$ is a real symmetric matrix and thus diagonalized. Without loss of generality we can assume that $\lambda_1(A(G)) \geq \lambda_2(A(G)) \geq \dots \geq \lambda_n(A(G))$.

Lemma 2.3. [1] Let \mathbb{C} be a CA where state transition matrix T and \mathbb{C}' be the complemented CA derived from \mathbb{C} where state transition operator \bar{T} . And let \bar{T}^p denote p times application of the complemented CA operator \bar{T} . Then

$$\bar{T}^p f(x) = [I \oplus T \oplus T^2 \oplus \dots \oplus T^{p-1}] F(x) \oplus T^p f(x)$$

$A(G)$ are $\lambda_1 = 4, \lambda_2 = \dots = \lambda_5 = 2, \lambda_6 = \dots = \lambda_{11} = 0, \lambda_{12} = \dots = \lambda_{15} = -2, \lambda_{16} = -4$. Therefore by Theorem 3.2 and Theorem 3.3 G is connected and bipartite. Fig. 2 shows the graph G with the adjacency matrix $A(G)$.

Theorem 4.3. *Let \mathbb{C} be the 60/102 NBCA whose state transition matrix is T . Let \mathbb{C}'_1 (resp. \mathbb{C}'_2) be the complemented CA derived from \mathbb{C} with the complement vector $F_1 = (0, *, \dots, *, 1)^t$ (resp. $F_2 = (1, *, \dots, *, 1)^t$). Also let $\overline{T}_1 X = TX \oplus F_1$ and $\overline{T}_2 X = TX \oplus F_2$. Let G_1 (resp. G_2) be the graph obtained from \mathbb{C}'_1 (resp. \mathbb{C}'_2). And let G be the union of two graphs G_1 and G_2 whose adjacency matrix is $A(G_1)$ and $A(G_2)$ respectively. Then G is a bipartite 4-regular graph.*

Table 1 shows the eigenvalue spectrum of $A(G)$ which is the union of G_1 and G_2 . In Table 1 let $F_1 = (0, 1, 1, 1)^t$ and $F_2 = (1, 1, 0, 1)^t$. Then the eigenvalue spectrum of $A(G)$ is $\lambda_1 = 4, \lambda_2 = \dots = \lambda_5 = 2, \lambda_6 = \dots = \lambda_{11} = 0, \lambda_{12} = \dots = \lambda_{15} = -2, \lambda_{16} = -4$. Therefore in this case the graph G is a bipartite 4-regular graph.

Table 2 shows the result of an experimentation performed with the 60/102 NBCA based regular graph. It measures the value of the two largest eigenvalues for random 60/102 NBCA based graphs for degree 4, 8, 12 and 16. Our results show that the spectral gap and hence the expansion increases proportionately with the number of union operations (t). Table 3 shows that the spectral gap by the our method is larger than the spectral gap by Mukhopadhyay's method [9].

Theorem 4.4. *Let \mathbb{C} be the n -cell 60/102 NBCA. Also let $\mathbf{x} = (x_1, x_2, \dots, x_n)^t$ be a state of the state transition diagram of the state transition matrix T of \mathbb{C} . Then the immediate predecessor $\mathbf{y} = (y_1, y_2, \dots, y_n)^t$ of \mathbf{x} satisfies the following:*

$$y_1 = x_1, y_n = x_n, y_k = x_k \oplus y_{k+1} \quad (k = 2, \dots, n-1)$$

Remark B. *It is easy to see that the inverse matrix T^{-1} of T is of the following form.*

$$T^{-1} = \begin{pmatrix} 1 & 0 & 0 & \dots & 0 & 0 & 0 \\ 0 & 1 & 1 & \dots & 1 & 1 & 1 \\ 0 & 0 & 1 & \dots & 1 & 1 & 1 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 & 1 & 1 \\ 0 & 0 & 0 & \dots & 0 & 1 & 1 \\ 0 & 0 & 0 & \dots & 0 & 0 & 1 \end{pmatrix}$$

So the required time to get the immediate predecessors is $O(n)$. For the given n -cell 60/102 NBCA, the construction of d -regular graphs which have the maximum spectral gaps depend on the relationship between F_1 and F_2 . For example, in Table 1 let $F_1 = (0, 0, 0, 1)^t$ and $F_2 = (1, 1, 1, 1)^t$. Then the spectral gap is 2 which is the maximum value in the 4-regular graph.

Now let

$$F_{11} = \{(0, a_2, a_3, \dots, a_{n-2}, 0, 1) | a_i \in \{0, 1\}, i = 2, \dots, n-2\}$$

$$F_{12} = \{(0, a_2, a_3, \dots, a_{n-2}, 1, 1) | a_i \in \{0, 1\}, i = 2, \dots, n-2\}$$

$$F_{21} = \{(1, a_2, a_3, \dots, a_{n-2}, 1, 1) | a_i \in \{0, 1\}, i = 2, \dots, n-2\}$$

$$F_{22} = \{(1, a_2, a_3, \dots, a_{n-2}, 0, 1) | a_i \in \{0, 1\}, i = 2, \dots, n-2\}$$

and let $U = (F_{11} \times F_{21}) \cup (F_{12} \times F_{22})$.

Tab. 1: The eigenvalue spectrum of $A(G)$. The eight vectors on the first row(resp. column) are the complement vectors F_1 (resp. F_2)

5	1.14	2
7	1.54	2.2857

Choose the complement vectors F_1, F_2 such that $(F_1, F_2) \in U$. Let G_1 (resp. G_2) be the graph with F_1 (resp. F_2). Then we can construct an expander graph where spectral gap is maximal.

The following algorithm shows computing the four neighbors of a vertex in G which is the union of G_1 and G_2 .

Algorithm (Computing neighbors of a vertex in G).

Input: Complement vectors $(F_1, F_2) \in K$ and a state $\mathbf{x} \in G$.

Output: The four neighbors (S_1, S_2, P_1, P_2) of \mathbf{x} .

Step 1: Find the next state S_1 (resp. S_2) of \mathbf{x} using the operator \bar{T}_1 (resp. \bar{T}_2).

$$S_1 = \bar{T}_1 \mathbf{x} = T\mathbf{x} \oplus F_1$$

$$S_2 = \bar{T}_2 \mathbf{x} = T\mathbf{x} \oplus F_2$$

/ Find the immediate predecessor P_1 (resp. P_2) by using Theorem 4.4 in Step 2 and Step 3 */*

Step 2: Compute $W := \mathbf{x} \oplus F_1$ and $V := \mathbf{x} \oplus F_2$.

Step 3: For $W = (w_1, w_2, \dots, w_n)$, $V = (v_1, v_2, \dots, v_n)$ and $k = 2, \dots, n-1$ find $P_1 := (p_{11}, p_{12}, \dots, p_{1n})$ and $P_2 := (p_{21}, p_{22}, \dots, p_{2n})$

$$p_{11} = w_1, \quad p_{1n} = w_n, \quad p_{1k} = w_k \oplus p_{1k+1}$$

$$p_{21} = v_1, \quad p_{2n} = v_n, \quad p_{2k} = v_k \oplus p_{2k+1}$$

In general the description of an expander d -regular graph grows exponentially with the number of vertices as the increase of the size of 60/102 NBCA. However as we require to store only two complement vectors F_1 and F_2 , this problem is solved by the above algorithm.

5 Conclusion

In this paper, we proposed a method to generate expander graphs with good expansion properties based on group 60/102 NBCA. The expansion properties by our method is better than the expansion properties proposed by Mukhopadhyay et al.
