received 12th Sep. 2012, revised 3rd June 2014, accepted 27th June 2014.

We study properties of infinite permutations generated by fixed points of some uniform binary morphisms, and find a precise formula for their complexity.

Keywords: infinite permutation, factor complexity, morphism

1 Introduction

A D0L word $\omega$ is an infinite word on a finite alphabet $\Sigma$ which is a fixed point of a morphism $\varphi : \Sigma^* \rightarrow \Sigma^*$, i.e., $\omega = \lim_{n \to \infty} \varphi^n(a)$ for $a \in \Sigma$. The class of D0L words has been extensively studied and contains famous words such as the cube-free Thue-Morse word and a square-free word on the three-letter alphabet. The subword complexity $C(n)$ of a word $\omega$ is the number of distinct words of length $n$ which occur in $\omega$. This function on infinite words has been studied in numerous papers; see, for instance, the survey Cassaigne and Nicolas (2010). The subword complexity of D0L words is well studied. For instance, in Cassaigne (1997), a general method for calculating the subword complexity of D0L words was developed, and in Frid (1998), the subword complexity of marked uniform D0L words was found. The subword complexity of the Thue-Morse word was found in Brlek (1989), Luca and Varricchio (1989), and later in Avgustinovich (1994).

In this paper we study infinite permutations generated by infinite D0L words. The notion of an infinite permutation was introduced in Fon-Der-Flaass and Frid (2007), where periodic properties and low complexity of permutations were investigated. Similarly to the definition of subword complexity of infinite words, we can introduce the factor complexity of a permutation as the number of its distinct subpermutations of a given length. Another complexity function called maximal pattern complexity of infinite permutations was investigated in Avgustinovich et al. (2011).

In this paper we study infinite permutations generated by infinite D0L words. The notion of an infinite permutation was introduced in Fon-Der-Flaass and Frid (2007), where periodic properties and low complexity of permutations were investigated. Similarly to the definition of subword complexity of infinite words, we can introduce the factor complexity of a permutation as the number of its distinct subpermutations of a given length. Another complexity function called maximal pattern complexity of infinite permutations was investigated in Avgustinovich et al. (2011).

The notion of a permutation generated by an infinite non-periodic word was introduced by Makarov (2006). In Makarov (2009) the same author calculated the factor complexity of permutations generated...
by the well-known family of Sturmian words. Widmer (2011) calculated the factor complexity of the
permuation generated by the Thue-Morse word.

In this paper we find a more general formula for the factor complexity of permutations generated by
fixed points of binary uniform morphisms from a wide class. In particular, since the Thue-Morse word
belongs to this class, we obtain an alternative way to compute the factor complexity of the Thue-Morse
permuation.

This paper is the extended and modified version of initial conference paper Valyuzhenich (2011). We
added proofs. Also we solve recurrent relations from Valyuzhenich (2011) and find the exact formula for
the permutation complexity. We calculate the permutation complexity for a wider class of morphisms.

In Section 2 we introduce basic definitions to be used below. In Section 3 we give the main ideas of
our proof. In Section 4 we introduce the class of morphisms $Q_l$ for which the main theorem of this paper
stated in Section 8 is valid. In Sections 5–7 we state some auxiliary statements needed to state and prove
the main theorem. In Section 9 we give an alternative proof of the formula for the factor complexity of
the Thue-Morse permuation.

2 Basic definitions

Let $\Sigma$ be a finite alphabet. Everywhere below we will use only the two-letter alphabet $\Sigma = \{0, 1\}$.

An infinite word over the alphabet $\Sigma$ is a word of the form $\omega = \omega_1\omega_2\omega_3 \ldots$, where $\omega_i \in \Sigma$. A (finite)
word $u$ is called a subword or factor of a (finite or infinite) word $v$ if $v = u_1 u_2$ for some words $u_1$ and
$u_2$ which may be empty. The length of a finite word $u$ is denoted by $|u|$. The set of all finite subwords of
the word $\omega$ is denoted by $F(\omega)$.

A mapping $h : \Sigma^* \rightarrow \Sigma^*$ is called a morphism if $h(xy) = h(x)h(y)$ for any words $x, y \in \Sigma^*$. We
say that $\omega$ is a fixed point of a morphism $\varphi$ if $\varphi(\omega) = \omega$. Clearly, every morphism is uniquely determined
by the images of letters, which are called blocks. A morphism is called $l$–uniform if its blocks are of the
same length $l$.

We say that a morphism $\varphi : \Sigma^* \rightarrow \Sigma^*$ is marked if its blocks are of the form $\varphi(a_i) = b_ix_ic_i$, where
$x_i$ is an arbitrary word, $b_i$ and $c_i$ are symbols of the alphabet $\Sigma$, and all $b_i$ (as well as all $c_i$) are distinct.
In what follows, we will consider only binary $l$–uniform marked morphisms.

We define $\varphi_{i,j}(v)$ as the word obtained from $\varphi(v)$ by erasing $i$ symbols to the left and $j$ symbols to the
right where $0 \leq i < l$ and $0 \leq j < l$. An interpretation of a word $u \in \Sigma^*$ under a morphism $\varphi$ is a
triple $s = (v, i, j)$, where $v = v_1 \ldots v_k$ is a word over the alphabet $\Sigma$, $i$ and $j$ are nonnegative integers
such that $0 \leq i < |\varphi(v_1)|$ and $0 \leq j < |\varphi(v_k)|$, and $u = \varphi_{i,j}(v)$. In addition, if $v$ is a subword of
$\omega = \varphi(\omega)$, then $s$ is called an interpretation on $\omega$. The word $v$ is called an ancestor of the word $u$.
In what follows we shall consider only interpretations on $\omega$. We say that $(u_1, u_2)$ is a synchronization point
(see Cassaigne (1994)) of $u \in F(\omega)$ if $u = u_1 u_2$ and $\forall v_1, v_2 \in \Sigma^*, \forall s \in F(\omega) \exists s_1, s_2 \in F(\omega)$ such that
$[v_1 u_2 = \varphi(s) \Rightarrow (s = s_1 s_2, v_1 u_1 = \varphi(s_1), u_2 v_2 = \varphi(s_2))]$. A fixed point $\omega = \varphi(\omega)$ of the morphism
$\varphi$ is called circular (see Cassaigne (1994)) with synchronization delay $L_\omega$, if $L_\omega$ is an integer such that
any subword $v$ of word $\omega$ of length at least $L_\omega$ contains at least one synchronization point.

Remark 1 If $\varphi$ is marked, then circularity of a word $\omega = \varphi(\omega)$ means that any of its subwords $u$ with
$|u| \geq L_\omega$ admits a unique interpretation on $\omega$: as we know a synchronization point, we can reconstruct
every block of this interpretation from its first (or last) symbol. Moreover for marked morphisms, this
means the uniqueness of the partition of the word $u$ with $|u| \geq L_\omega$ into blocks.
An occurrence of a word \( u \in \Sigma^* \) in the word \( \omega \) is a pair \((u, m)\) such that \( u = \omega_{m+1} \omega_{m+2} \ldots \omega_{m+n} \).

It is easy to see that a word can have many different occurrences. Let \( \omega = \varphi(\omega) \). An occurrence \((v, p)\) of a word \( v \) of length \( k \) is called the ancestor of an occurrence \((u, m)\) of the word \( u \) if there exists an interpretation \((v, i, j)\) of \( u \) such that \( m = pl + i \).

**Remark 2** Let \( \varphi \) be a marked morphism. Then by Remark 2, circularity of a word \( \omega = \varphi(\omega) \) means that any of its subwords \( u \) with \( |u| \geq L_\omega \) admits a unique interpretation \((v, i, j)\) on \( \omega \). So if \( u \) is a subword of \( \omega \) with \( |u| \geq L_\omega \), then interpretations of all occurrences of \( u \) are the same and equal to \((v, i, j)\).

Now we introduce the main object of this paper. Let \( A_N \) be the set of all sequences of pairwise distinct reals defined on \( \mathbb{N} = \{0, 1, 2, \ldots \} \). Define an equivalence relation \( \sim \) on \( A_N \) as follows: let \( a, b \) be sequences from \( A_N \), where \( a = \{a_s\}_{s \in \mathbb{N}} \) and \( b = \{b_s\}_{s \in \mathbb{N}} \); then \( a \sim b \) if and only if for all \( s, r \in \mathbb{N} \) the inequalities \( a_s < a_r \) and \( b_s < b_r \) hold or do not hold simultaneously. An equivalence class from \( A_N/\sim \) is called an \((N)\)-permutation, or a one-sided infinite permutation. If a permutation \( \alpha \) is realized by a sequence of reals \( a \), that is, if the sequence \( a \) belongs to the class \( \alpha \), we denote \( \alpha = \pi \). Similarly, we can consider a \( \mathbb{Z} \)-permutation, or an \( S \)-permutation, defined on an arbitrary subset \( S \) of \( \mathbb{Z} \). In particular, a \( \{1, \ldots, n\}\)-permutation always has a representative with all values in \( \{1, \ldots, n\} \), i.e., can be identified with a usual permutation from \( S_n \). In what follows the notation \( x = x_1 \ldots x_n \), where \( x_i \in \{1, \ldots, n\} \), \( x_i \neq x_j \) for \( i \neq j \), means that the sequence \( x_1, \ldots, x_n \) is a representative of the permutation \( x \), that is, that \( x = x_1 \ldots x_n \).

Let \( \omega \) be an infinite nonperiodic word over the alphabet \( \Sigma \). A word \( \omega \) corresponds to the binary real number \( R_\omega(i) = 0, \omega_i \omega_{i+1} \ldots = \sum_{k \geq 0} \omega_{i+k}2^{-(k+1)} \). We will say that the infinite permutation \( \alpha_\omega \) is generated by \( \omega \) if it is realized by the sequence of \( \alpha_i = R_\omega(i) \).

Since \( \omega \) is a non-periodic word, all \( R_\omega(i) \) are distinct, and the definition above is correct.

We define a function \( \gamma : \mathbb{R}^2 \setminus \{(a, a) | a \in \mathbb{R}\} \rightarrow \{<, >\} \), which for two different real numbers reveals their relation: \( \gamma(a, b) = < \) if and only if \( a < b \). We say that a permutation \( \pi = \pi_1 \ldots \pi_n \) is a subpermutation or factor of length \( n \) of an infinite permutation \( \alpha_\omega \) if \( \gamma(\pi_s, \pi_t) = \gamma(\alpha_{i+s}, \alpha_{i+t}) \) for \( 1 \leq s < t \leq n \) and for a fixed positive integer \( i \). In this case we write that \( \pi = \alpha_{i+1} \ldots \alpha_{i+n} \).

We define the set \( \text{Perm}(n) \) as the set of all subpermutations of \( \alpha_\omega \) of length \( n \):

\[
\text{Perm}(n) = \{\alpha_{i+1} \ldots \alpha_{i+n} | i \geq 0\}.
\]

Now we define the permutation complexity of a word \( \omega \) (or equivalently, the factor complexity of the induced permutation \( \alpha_\omega \)) as \( \lambda(n) = |\text{Perm}(n)| \). We say that an occurrence \((u, m)\) of a word \( u \) of length \( n \) generates a permutation \( \pi = \pi(u, m) \) if \( \alpha_{m+1} \ldots \alpha_{m+n} = \pi \). A subword \( u \) of the word \( \omega \) generates a permutation \( \pi \) if there is an occurrence \((u, m)\) of this word which generates \( \pi \). The number of permutations generated by \( u \) is denoted by \( f(u) \).

## 3 General scheme

The main idea of the proof is that we calculate \( \sum_{|u| = n} f(u) \). We note that \( \sum_{|u| = n} f(u) \) is the number of permutations, each of them generated by at least one occurrence of some subword of length \( n \) of word \( \omega \). It is clear that some permutations can be calculated several times. But in [Makarov (2006)] it was proved that two distinct subwords \( u_1 \) and \( u_2 \) of word \( \omega \) can generate the same permutations if and only if \( u_1 = v0 \) and \( u_2 = v1 \) up to a relabeling of \( u_1 \) and \( u_2 \). Recall that a subword \( v \) of the word \( \omega \) is called special (in
Let \( \omega \) if \( v0 \) and \( v1 \) are also subwords of \( \omega \). The set of all the special words of length \( n \) is denoted by \( B(n) \). Thus permutation complexity of \( \omega \) is

\[
\sum_{|u|=n} f(u) - \sum_{b \in B(n-1)} g(b),
\]

where \( g(v) \) is the number of common permutations generated by some occurrences of words \( v0 \) and \( v1 \).

After we prove that we can express \( f(u) \) through \( f(u') \), where \( u' \) is the ancestor of \( u \). We also show that we can express \( g(v) \) through \( g(v') \), where \( v' \) is the ancestor of \( v \) and \( v \) is a special word. So we reduce the calculation of \( \sum_{|u|=n} f(u) \) and \( \sum_{b \in B(n-1)} g(b) \) to the calculation of \( \sum_{|u|=k} f(u) \) and \( \sum_{b \in B(k-1)} g(b) \), where \( k \) is a sufficiently small number.

4 Class \( Q_l \)

We say that a \( l \)-uniform marked binary morphism \( \varphi \) such that \( \varphi(0) \) starts with 0 belongs to the class \( Q_l \) if it satisfies the following properties (we assume that \( l \geq 2 \)):

**Properties.**

1. If \( \varphi(0) = 0u0x \) for some word \( x \), then \( 0u1 \) is not a subword of \( \varphi(0) \) and \( \varphi(1) \) and \( 0u \) is not a suffix of \( \varphi(0) \) and \( \varphi(1) \).

2. If \( \varphi(1) = 1u1x \) for some word \( x \), then \( 1u0 \) is not a subword of \( \varphi(0) \) and \( \varphi(1) \) and \( 1u \) is not a suffix of \( \varphi(0) \) and \( \varphi(1) \).

In [Frid (1998)] the criterion of circularity of marked uniform morphisms was obtained. According to an easy corollary of that criterion [Frid (2000)], all nonperiodic fixed points of \( l \)-uniform binary morphisms with \( \omega_1 = 0 \) are circular, except for the case when \( \varphi(1) = 1^l \). So \( \omega = \lim_{n \to \infty} \varphi^n(0) \) of any morphism \( \varphi \) which belongs to the class \( Q_l \) is circular because \( \varphi(1) \neq 1^l \) (if \( \varphi(1) = 1^l \), then we obtain a contradiction with Property 2 in the definition of \( Q_l \)).

Everywhere below the word \( \varphi(0) \) will be called the block of the first type, and \( \varphi(1) \) is called the block of the second type.

**Example.** Each morphism \( \varphi(0) = 01^{2n}01^n, \varphi(1) = 10^{2n}10^n \) for \( n \geq 2 \) belongs to \( Q_l \), whereas the morphism \( \varphi(0) = 01011, \varphi(1) = 10000 \) does not belong to \( Q_l \).

Consider a fixed point \( \omega = \varphi(\omega) \) of a morphism \( \varphi \in Q_l \). The partition of \( \omega \) into blocks which are the images of its symbols is called correct.

Let \( u \) and \( v \) be two words such that \( |u| = |v| \). We say that \( u > v \) (or \( v < u \)) if \( u = u_1u_2 \) and \( v = u_1v_2 \) for some words \( u_1, u_2 \) and \( v_2 \).

**Lemma 1** Let \( \omega \) be a fixed point of the morphism \( \varphi \), where \( \varphi \in Q_l \). Then the following statements are true:

1. Let \( \omega_i = \omega_j = 0 \) and \( i \equiv 1 \pmod{l}, j \not\equiv 1 \pmod{l} \). Then \( R_{\omega}(i) > R_{\omega}(j) \).
2. Let \( \omega_i = \omega_j = 1 \) and \( i \equiv 1 \pmod{l}, j \not\equiv 1 \pmod{l} \). Then \( R_{\omega}(i) < R_{\omega}(j) \).

To prove Lemma [1] we prove several auxiliary assertions.
Proposition 1 Let $\varphi \in Q_l$. Then the following statements are true:

1. If $0u$ is a prefix of $\varphi(0)$ and $0v$ is a subword of $\varphi(0)$ or $\varphi(1)$ with $|u| = |v|$, then $v < u$ or $v = u$.

2. If $1u$ is a prefix of $\varphi(1)$ and $1v$ is a subword of $\varphi(0)$ or $\varphi(1)$ with $|u| = |v|$, then $v > u$ or $v = u$.

Proof: The two cases are symmetric, so we shall prove the first one. Let $v > u$. Hence $v = u_11v_2$ and $u = u_10u_2$ for some words $u_1, u_2$ and $v_2$. So $0u_10$ is a prefix of $\varphi(0)$ and $0u_11$ is a subword of $\varphi(0)$ or $\varphi(1)$. It contradicts with Property 1 of the definition of $Q_l$. □

Proposition 2 Let $\omega$ be a some binary nonperiodic word. Let $R_\omega(i) = 0, xu \ldots$ and $R_\omega(j) = 0, xv \ldots$ for some finite words $x, u$ and $v$ such that $u > v$. Then $R_\omega(i) > R_\omega(j)$.

Proof: Since $u > v$, we have $u = u_11u_2$ and $v = u_10u_2$ for some words $u_1, u_2$ and $v_2$. So $u \equiv_1 v$ and $v < u$. Consider the case when $u' < u$. Then we have $\gamma(R_\omega(i), R_\omega(j)) = \gamma(0, xu_1 \ldots; 0, xu_10 \ldots) = >$ due to Proposition 1.

Proof of Lemma 1 The two cases are symmetric, so we shall prove the first one. Since $\omega_i = 0$ and $i \equiv 1 \pmod{l}$, $\omega_i$ lies in block $\varphi(0)$ in the correct partition of $\omega$ into blocks. Let $\omega_j$ lie in block $\varphi(c)$ in the correct partition of $\omega$ into blocks for some $c \in \{0, 1\}$. There exist words $u, u', x$ and $y$ such that $\varphi(0) = 0uy$, $\varphi(c) = x\omega_ju'$ and $|u| = |u'|$.

Proposition 1 implies that $u' < u$ or $u' = u$. Consider the case when $u' < u$. Then we have $\gamma(R_\omega(i), R_\omega(j)) = \gamma(0, xu_1 \ldots; 0, xu_10 \ldots) = >$ due to Proposition 2. Consider the case when $u = u'$. Then $\varphi(c) = x\omega_ju$. Let $\varphi(0) = 0uv$ for some letter $a$ and word $v$. Since $0u$ is a suffix of $\varphi(c)$, by Property 1 of the definition of $Q_l$ we have that $a = 1$. So $\varphi(0) = 0u1v$. If $\omega_j+|u|+1 = 0$, then $\gamma(R_\omega(i), R_\omega(j)) = \gamma(0, \omega_ju1 \ldots; 0, \omega_ju0 \ldots) = >$.

Consider the case when $\omega_j+|u|+1 = 1$. Since $\varphi(c) = x\omega_ju$, we have $j + |u| + 1 \equiv 1 \pmod{l}$ and $\omega_j+|u|+1$ lies in block $\varphi(1)$ in the correct partition $\omega$ into blocks. Let $\varphi(1) = 1v's$, where $v'$ and $s$ are some words and $b$ is a letter such that $|v| = |v'|$. Hence $|s| = |u|$. By Proposition 1 we have $v' < v$ or $v = v'$. If $v' < v$, then $\gamma(R_\omega(i), R_\omega(j)) = \gamma(0, \omega_ju1v \ldots; 0, \omega_ju1v' \ldots) = >$ due to Proposition 2. So we can assume that $v = v'$. Since $1v$ is a suffix of $\varphi(0)$, by Property 2 of the definition of $Q_l$ we have that $b = 0$. If $\omega_{i+l} = 1$, then $\gamma(R_\omega(i), R_\omega(j)) = \gamma(0, \omega_iu1v1 \ldots; 0, \omega_ju1v0 \ldots) = >$.

So we can assume that $\omega_{i+l} = 0$. Since $i \equiv 1 \pmod{l}$, we have $i+l \equiv 1 \pmod{l}$ and $\omega_{i+l}$ lies in block $\varphi(0)$ in the correct partition $\omega$ into blocks. By Proposition 1 we have $s < u$ or $s = u$. If $s < u$, then $\gamma(R_\omega(i), R_\omega(j)) = \gamma(0, \omega_iu1v0 \ldots; 0, \omega_ju1vs \ldots) = >$.
we can assume that \( s = u \). If \( \omega_{j+|u|+l+1} = 0 \), then
\[
\gamma(R_\omega(i), R_\omega(j)) = \gamma(0, \omega_i u 1 v 0 u 1 \ldots ; 0, \omega_j u 1 v 0 u 0 \ldots ) = \rangle.
\]
So we can assume that \( \omega_{j+|u|+l+1} = 1 \).

Continuing the procedure, we obtain that either \( R_\omega(i) > R_\omega(j) \), or \( \omega = \omega_1 \ldots \omega_{i-1} \varphi(0) \varphi(0) \ldots \). The second case is impossible because word \( \omega \) is nonperiodic.

**Lemma 2** Let \( \omega \) be a fixed point of the morphism \( \varphi \), where \( \varphi \in Q_l \). Let \( \omega_i = \omega_j \), where \( i \equiv i' \pmod l \), \( j \equiv j' \pmod l \) and \( 0 \leq i', j' \leq l - 1 \). If \( i' \neq j' \), or if \( \omega_i \) and \( \omega_j \) lie in blocks of different types in the correct partition of \( \omega \) into blocks, then the relation \( \gamma(R_\omega(i), R_\omega(j)) \) is uniquely defined by \( i' \), \( j' \) and the types of respective blocks.

**Proof:** Let \( \omega_i \) and \( \omega_j \) lie in blocks of different types in the correct partition of \( \omega \) and \( i' = j' \). Without loss of generality, we assume that \( \omega_i \) lies in \( \varphi(0) \) and \( \omega_j \) lies in \( \varphi(1) \). Then \( \varphi(0) = x\omega_i y \) and \( \varphi(1) = x'\omega_j y' \) where \(|y| = |y'|\). Since the last symbols of \( y \) and \( y' \) are different, we have \( y = zav \) and \( y' = zbv' \) where \( a \) and \( b \) are different symbols. Hence we obtain that
\[
\gamma(R_\omega(i), R_\omega(j)) = \gamma(0, \omega_i za \ldots ; 0, \omega_j zb \ldots ) = \gamma(a, b).
\]

In all other cases we have \( i' \neq j' \). Without loss of generality, we assume that \( i' < j' \). Let \( T_1 = x\omega_i y \) and \( T_2 = x'\omega_j y' \) be blocks which contain \( \omega_i \) and \( \omega_j \). Then there are two cases. In the first case we have \( y = y''z \) where \(|y''| = |y'| \) and \( y'' \neq y' \). Hence we obtain that \( y'' = gav'' \), \( y' = gbv' \) where \( g, g', g'' \) are some words, \( a \) and \( b \) are different symbols. Hence we obtain that
\[
\gamma(R_\omega(i), R_\omega(j)) = \gamma(0, \omega_i ga \ldots ; 0, \omega_j gb \ldots ) = \gamma(a, b).
\]

In the second case we have \( y = y'z \). Assume first that \( z = 0z' \) for some word \( z' \). If \( \omega_{j+l-j'-1} = 0 \), then Lemma[4] implies that \( R_\omega(i + |y'| + 1) < R_\omega(j + l - j' + 1) \), because in this case \( \omega_{j+l-j'-1} = 0 \) and \( j + l - j' + 1 \equiv 1 \pmod l \). If \( \omega_{j+l-j'-1} = 1 \), then \( R_\omega(i + |y'| + 1) < R_\omega(j + l - j' + 1) \). In addition, we have that
\[
\gamma(R_\omega(i), R_\omega(j)) = \gamma(0, \omega_i y'0 \ldots ; 0, \omega_j y'0 \ldots ) = \gamma(R_\omega(i + |y'| + 1), R_\omega(j + l - j' + 1)).
\]

Thus, in this case the inequality \( R_\omega(i) < R_\omega(j) \) always holds.

It remains to consider the case \( z = 1z' \). If \( \omega_{j+l-j'-1} = 1 \), then Lemma[4] implies that \( R_\omega(i + |y'| + 1) > R_\omega(j + l - j' + 1) \), because in this case \( \omega_{j+l-j'-1} = 1 \) and \( j + l - j' + 1 \equiv 1 \pmod l \). If \( \omega_{j+l-j'-1} = 0 \), then \( R_\omega(i + |y'| + 1) > R_\omega(j + l - j' + 1) \). In addition, we have that
\[
\gamma(R_\omega(i), R_\omega(j)) = \gamma(0, \omega_i y'1 \ldots ; 0, \omega_j y'1 \ldots ) = \gamma(R_\omega(i + |y'| + 1), R_\omega(j + l - j' + 1)).
\]

Thus, in this case the inequality \( R_\omega(i) > R_\omega(j) \) always holds. \( \square \)

**Lemma 3** Let \( (u, n_1) \) and \( (u, n_2) \) be two occurrences of a subword \( u \) of length \( n \geq L_\omega \), \( (u', m_1') \) and \( (u', m_2') \) be their ancestors. Then for \( 1 \leq i < s \leq n \) either
\[
\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) = \gamma(R_\omega(m_2 + t), R_\omega(m_2 + s))
\]
or $m_1 + t = (m'_1 + t' - 1)l + r$, $m_1 + s = (m'_1 + s' - 1)l + r$, $m_2 + t = (m'_2 + t' - 1)l + r$, $m_2 + s = (m'_2 + s' - 1)l + r$ for some $1 \leq r \leq l$ and

$$\omega_{m'_1 + t'} = \omega_{m'_1 + s'} = \omega_{m'_2 + t'} = \omega_{m'_2 + s'}.$$ 

**Proof:** Let $1 \leq t < s \leq n$. Consider relations $\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s))$ and $\gamma(R_\omega(m_2 + t), R_\omega(m_2 + s))$. If $\omega_{m_1 + t} \neq \omega_{m_1 + s}$ and $\omega_{m_2 + t} \neq \omega_{m_2 + s}$, then

$$\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) = \gamma(\omega_{m_1 + t}, \omega_{m_1 + s})$$

and

$$\gamma(R_\omega(m_2 + t), R_\omega(m_2 + s)) = \gamma(\omega_{m_2 + t}, \omega_{m_2 + s}).$$

So

$$\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) = \gamma(R_\omega(m_2 + t), R_\omega(m_2 + s)).$$

Consider the case when $\omega_{m_1 + t} = \omega_{m_1 + s}$ and $\omega_{m_2 + t} = \omega_{m_2 + s}$. Let $u_1 = \omega_{m_1 + 1} \ldots \omega_{m_1 + n}$ and $u_2 = \omega_{m_2 + 1} \ldots \omega_{m_2 + n}$. Since $|u_1| = |u_2| \geq L_\omega$, by Remark 1 words $u_1$ and $u_2$ have the same partitions in the correct partition of $\omega$. Hence $\omega_{m_1 + t}$, $\omega_{m_1 + s}$, $\omega_{m_2 + t}$ and $\omega_{m_2 + s}$ lie in blocks $\varphi(\omega_{m'_1 + t'})$, $\varphi(\omega_{m'_1 + s'})$, $\varphi(\omega_{m'_2 + t'})$ and $\varphi(\omega_{m'_2 + s'})$ in the correct partition of $\omega$ for some $1 \leq t' < s' \leq |\omega|$. Moreover $\omega_{m_1 + t}$ and $\omega_{m_2 + t}$ occur in blocks $\varphi(\omega_{m'_1 + t'})$ and $\varphi(\omega_{m'_2 + t'})$ at the same positions. Analogously $\omega_{m_1 + s}$ and $\omega_{m_2 + s}$ occur in blocks $\varphi(\omega_{m'_1 + s'})$ and $\varphi(\omega_{m'_2 + s'})$ at the same positions. So $m_1 + t \equiv m_2 + t \pmod{l}$ and $m_1 + s \equiv m_2 + s \pmod{l}$. Moreover $\omega_{m'_1 + t'} = \omega_{m'_2 + t'}$ and $\omega_{m'_1 + s'} = \omega_{m'_2 + s'}$.

Let

$$\omega_{m'_1 + t'} = \omega_{m'_1 + t'} = a$$

and

$$\omega_{m'_1 + s'} = \omega_{m'_2 + s'} = b.$$ 

If $a \neq b$, then $\omega_{m_1 + t}$ and $\omega_{m_1 + s}$ (as $\omega_{m_2 + t}$ and $\omega_{m_2 + s}$) lie in blocks of different types in the correct partition of $\omega$ into blocks. Since $m_1 + t \equiv m_2 + t \pmod{l}$ and $m_1 + s \equiv m_2 + s \pmod{l}$, Lemma 2 implies that

$$\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) = \gamma(R_\omega(m_2 + t), R_\omega(m_2 + s)).$$

If $a = b$ and $s \neq t \pmod{l}$, then $m_1 + t \neq m_1 + s \pmod{l}$, $m_2 + t \neq m_2 + s \pmod{l}$ and Lemma 2 also implies that

$$\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) = \gamma(R_\omega(m_2 + t), R_\omega(m_2 + s)).$$

It remains to consider the case when $a = b$ and $s \equiv t \pmod{l}$. Then

$$\omega_{m'_1 + t'} = \omega_{m'_2 + t'} = \omega_{m'_2 + s'}.$$ 

Moreover since $s \equiv t \pmod{l}$, we have $m_1 + t = (m'_1 + t' - 1)l + r$, $m_1 + s = (m'_1 + s' - 1)l + r$, $m_2 + t = (m'_2 + t' - 1)l + r$ and $m_2 + s = (m'_2 + s' - 1)l + r$ for some $1 \leq r \leq l$. □

**Lemma 4** Let $\omega_i = \omega_j$ and $R_\omega(i) < R_\omega(j)$. Then the inequalities $R_\omega((i - 1)l + r) < R_\omega((j - 1)l + r)$ hold for all $1 \leq r \leq l$. 

Proof: Since \( \omega_i = \omega_j \), we obtain that \( \phi(\omega_i) = \phi(\omega_j) \). Hence we have that the equality \( \omega(i-1)+r = \omega(j-1)+r \) holds for all \( 1 \leq r \leq l \). Since \( R_\omega(i) < R_\omega(j) \) then there exists a finite binary word \( x \) such that \( R_\omega(i) = 0, \omega_i x 0 \ldots \) and \( R_\omega(j) = 0, \omega_j x 1 \ldots \). Hence we have

\[
R_\omega(i-1)+r = 0, \omega(i-1)+r \ldots \omega_l \phi(x) 0 \ldots
\]

and

\[
R_\omega(j-1)+r = 0, \omega(j-1)+r \ldots \omega_j \phi(x) 1 \ldots
\]

Consequently we obtain that \( R_\omega((i-1)+r) < R_\omega((j-1)+r) \). The lemma is proved. \( \square \)

Lemma 5 Let \((v_0, m_1)\) and \((v_1, m_2)\) be some occurrences of words \(v_0\) and \(v_1\) with \(|v| = n \geq L_\omega\) and let \((v_0', m_1')\) and \((v_1', m_2')\) be their ancestors with \(|v'| = k\). Then the following statements are true:

1. If \( m_1 + t \neq 1 \pmod{l} \) and \( m_2 + t \neq 1 \pmod{l} \), then

\[
\gamma(R_\omega(m_1+t), R_\omega(m_1+n+1)) = \gamma(R_\omega(m_2+t), R_\omega(m_2+n+1))
\]

for \( 1 \leq t < n + 1 \).

2. If \( m_1 + t = (m_1' + t' - 1)l + 1 \) and \( m_2 + t = (m_2' + t' - 1)l + 1 \) for \( 1 \leq t' < k + 1 \) and \( 1 \leq t < n + 1 \), then

\[
\gamma(R_\omega(m_1+t), R_\omega(m_1+n+1)) = \gamma(R_\omega(m_2+t), R_\omega(m_2+n+1))
\]

if and only if

\[
\gamma(R_\omega(m_1'+t'), R_\omega(m_1'+k+1)) = \gamma(R_\omega(m_2'+t'), R_\omega(m_2'+k+1))
\]

Proof: Let \( 1 \leq t < n + 1 \). Let \( v_1 = \omega_{m_1+1} \ldots \omega_{m_1+n} \) and \( v_2 = \omega_{m_2+1} \ldots \omega_{m_2+n} \). Since \( |v_1| = |v_2| \geq L_\omega \), by Remark [4] words \( v_1 \) and \( v_2 \) have the same partitions in the correct partition of \( \omega \). Hence \( \omega_{m_1+t} \) and \( \omega_{m_2+t} \) lie in blocks \( \phi(\omega_{m_1'+t'}) \) and \( \phi(\omega_{m_2'+t'}) \) in the correct partition of \( \omega \) for some \( 1 \leq t' \leq k \). Moreover \( \omega_{m_1+t} \) and \( \omega_{m_2+t} \) occur in blocks \( \phi(\omega_{m_1'+t'}) \) and \( \phi(\omega_{m_2'+t'}) \) at the same positions. So \( m_1 + t \equiv m_2 + t \pmod{l} \). Since \( v \) is a special word, \( v \) has the interpretation \((v', i, 0)\), where \( 0 \leq i < l \). Hence the last blocks of partitions of \( v_1 \) and \( v_2 \) in the correct partition of \( \omega \) are complete. So \( m_1 + n + 1 \equiv 1 \pmod{l} \) and \( m_2 + n + 1 \equiv 1 \pmod{l} \). Since \( \omega_{m_1+n+1} = 0 \) and \( \omega_{m_2+n+1} = 1 \), we have that \( \omega_{m_1+n+1} \) and \( \omega_{m_2+n+1} \) are the first symbols of blocks \( \phi(\omega_{m_1'+k+1}) = \phi(0) \) and \( \phi(\omega_{m_2'+k+1}) = \phi(1) \) in the correct partition of \( \omega \). Hence \( m_1 + n + 1 = (m_1' + k)l + 1 \), \( m_2 + n + 1 = (m_2' + k)l + 1 \) and \( \omega_{m_1'+k+1} = 0 \), \( \omega_{m_2'+k+1} = 1 \).

Consider the case when \( m_1 + t \neq 1 \pmod{l} \) and \( m_2 + t \neq 1 \pmod{l} \). Assume that

\[
\omega_{m_1+t} = \omega_{m_2+t} = 0
\]

(the other case is similar). Recall that \( \omega_{m_1+n+1} = 0 \). Since \( m_1 + t \neq 1 \pmod{l} \) and \( m_1 + n + 1 \equiv 1 \pmod{l} \), we have that \( R_\omega(m_1+t) < R_\omega(m_1+n+1) \) due to Lemma [4] Since \( \omega_{m_2+t} = 0 \) and \( \omega_{m_2+n+1} = 1 \), we have that

\[
\gamma(R_\omega(m_2+t), R_\omega(m_2+n+1)) = \gamma(0,0\ldots;0,1\ldots) = < .
\]
So
\[ \gamma(R'_\omega(m_1 + t), R'_\omega(m_1 + n + 1)) = \gamma(R'_\omega(m_2 + t), R'_\omega(m_2 + n + 1)). \]

Consider the case when \( m_1 + t \equiv 1 \pmod{l} \) and \( m_2 + t \equiv 1 \pmod{l} \). As we note above \( \omega_{m_1+t} \) and \( \omega_{m_2+t} \) lie in blocks \( \varphi(\omega_{m_1'+t'}) \) and \( \varphi(\omega_{m_2'+t'}) \) in the correct partition of \( \omega \) for some \( 1 \leq t' < k + 1 \). Hence \( m_1 + t = (m_1' + t' - 1)l + 1 \) and \( m_2 + t = (m_2' + t' - 1)l + 1 \). Assume that
\[ \omega_{m_1+t} = \omega_{m_2+t} = 0 \]
(the case when \( \omega_{m_1+t} = \omega_{m_2+t} = 1 \) is similar). Since \( \varphi(0) \) starts with 0 and \( \varphi(1) \) starts with 1, we have that \( \omega_{m_1'+t'} = \omega_{m_2'+t'} = 0 \). Recall that \( \omega_{m_2+n+1} = \omega_{m_2+k+1} = 1 \). Then
\[ \gamma(R'_\omega(m_2 + t), R'_\omega(m_2 + n + 1)) = \gamma(R'_\omega(m_2' + t'), R'_\omega(m_2' + k + 1)). \]

Lemma 4 implies that
\[ \gamma(R'_\omega(m_1 + t), R'_\omega(m_1 + n + 1)) = \gamma(R'_\omega(m_1' + t'), R'_\omega(m_1' + k + 1)). \]
So
\[ \gamma(R'_\omega(m_1 + t), R'_\omega(m_1 + n + 1)) = \gamma(R'_\omega(m_2 + t), R'_\omega(m_2 + n + 1)) \]
if and only if
\[ \gamma(R'_\omega(m_1' + t'), R'_\omega(m_1' + k + 1)) = \gamma(R'_\omega(m_2' + t'), R'_\omega(m_2' + k + 1)). \]

\[ \square \]

5 Conjugacy of permutations

In this section we introduce the concept of conjugate permutations. Let \( z = z_1 z_2 \ldots z_k \) be a permutation of length \( k \), where \( z_i \in \{1, 2, \ldots, k\} \).

An element of the permutation \( z \) is the number \( z_i \), where \( 1 \leq i \leq k \).

We will say that two permutations \( x = x_1 x_2 \ldots x_k \) and \( y = y_1 y_2 \ldots y_k \) are conjugate if they differ only in relations of extreme elements, i.e \( \gamma(x_1, x_k) \neq \gamma(y_1, y_k) \), but \( \gamma(x_i, x_j) = \gamma(y_i, y_j) \) for all other \( i, j \). We will denote this conjugacy by \( x \sim y \).

Example. There are exactly two pairs of conjugate permutations among the permutations of length \( 3: 132 \sim 231 \) and \( 213 \sim 312 \).

Lemma 6 Let \( x \) be a finite permutation and \( x = x_1 \ldots x_k \). Then a permutation \( y \) such that \( x \sim y \) exists if and only if \( |x_1 - x_k| = 1 \).

Proof: Let us prove the necessity. Let \( y \) be a permutation such that \( x \sim y \). Let us prove that \( |x_1 - x_k| = 1 \). If it is not true, then there exists \( 1 < i < k \) such that \( \min(x_1, x_k) < x_i < \max(x_1, x_k) \). Since \( x \sim y \), we obtain that \( \gamma(x_1, x_k) = \gamma(y_1, y_k) \) and \( \gamma(x_i, x_k) = \gamma(y_i, y_k) \). Hence \( \gamma(x_1, x_k) = \gamma(y_1, y_k) \). It contradicts with \( x \sim y \).

Let us prove the sufficiency. Let \( |x_1 - x_k| = 1 \). We construct a permutation \( y \) as follows: let \( y_1 = x_k, y_k = x_1, y_2 = x_2, y_3 = x_3, \ldots, y_{k-1} = x_{k-1} \). Since \( |x_1 - x_k| = 1 \), we obtain that \( \gamma(x_i, x_j) = \gamma(y_i, y_j) \) for all \( i, j \) except \( i = 1, j = k \). On the other hand, we have by construction that \( \gamma(x_1, x_k) \neq \gamma(y_1, y_k) \), that is \( x \sim y \). \( \square \)
Lemma 7  Let $(u, m_1)$ and $(u, m_2)$ be two occurrences of a subword $u$ of length $n \geq L_\omega$, and $(u', m'_1)$ and $(u', m'_2)$ be their ancestors with $|u'| = k$. Then the following statements are true:

1. If $\pi(u, m_1) \neq \pi(u, m_2)$, then $\pi(u', m'_1) \neq \pi(u', m'_2)$.

2. If $\pi(u, m_1) \sim \pi(u, m_2)$, then $\pi(u', m'_1) \sim \pi(u', m'_2)$ and $n = (k-1)l + 1$.

3. If $\pi(u', m'_1) \neq \pi(u', m'_2)$ and $\pi(u', m'_1) \sim \pi(u', m'_2)$, then $\pi(u, m_1) \neq \pi(u, m_2)$ and $\pi(u, m_1) \sim \pi(u, m_2)$.

4. If $n = (k-1)l + 1$ and $\pi(u', m'_1) \sim \pi(u', m'_2)$, then $\pi(u, m_1) \sim \pi(u, m_2)$.

5. If $n < (k-1)l + 1$ and $\pi(u', m'_1) \sim \pi(u', m'_2)$, then $\pi(u, m_1) = \pi(u, m_2)$.

6. If $n > (k-1)l + 1$ and $\pi(u', m'_1) \sim \pi(u', m'_2)$, then $\pi(u, m_1) \neq \pi(u, m_2)$.

Proof: Let $u$ have the interpretation $(u', i, j)$, where $0 \leq i < l$, $0 \leq j < l$. It is unique since $|u| \geq L_\omega$.

1. Consider $1 \leq t < s \leq n$. Lemma 3 implies that either

$$\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) = \gamma(R_\omega(m_2 + t), R_\omega(m_2 + s))$$

or $m_1 + t = (m'_1 + t' - 1)l + r$, $m_1 + s = (m'_1 + s' - 1)l + r$, $m_2 + t = (m'_2 + t' - 1)l + r$, $m_2 + s = (m'_2 + s' - 1)l + r$ for some $1 \leq r \leq l$ and

$$\omega_{m'_1 + t'} = \omega_{m'_1 + s'} = \omega_{m'_2 + t'} = \omega_{m'_2 + s'}.$$

Consider the second case. Then Lemma 4 implies that

$$\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) = \gamma(R_\omega(m'_1 + t'), R_\omega(m'_1 + s'))$$

and

$$\gamma(R_\omega(m_2 + t), R_\omega(m_2 + s)) = \gamma(R_\omega(m'_2 + t'), R_\omega(m'_2 + s')).$$

Since $\pi(u, m_1) \neq \pi(u, m_2)$, we obtain that

$$\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) \neq \gamma(R_\omega(m_2 + t), R_\omega(m_2 + s))$$

for some $1 \leq t < s \leq n$. Then we have

$$\gamma(R_\omega(m'_1 + t'), R_\omega(m'_1 + s')) \neq \gamma(R_\omega(m'_2 + t'), R_\omega(m'_2 + s'))$$

for the corresponding $t'$ and $s'$. Hence we prove that $\pi(u', m'_1) \neq \pi(u', m'_2)$.

2. Since $(u', m'_1)$ is the ancestor of $(u, m_1)$, we obtain that $m_1 + 1 = m'_1 l + i + 1$ and $m_1 + n = (m'_1 + k)l - j$. So $n = kl - i - j$. Since $\pi(u, m_1) \sim \pi(u, m_2)$, we have

$$\gamma(R_\omega(m_1 + 1), R_\omega(m_1 + n)) \neq \gamma(R_\omega(m_2 + 1), R_\omega(m_2 + n)).$$

Hence Lemma 3 implies that $m_1 + 1 = m'_1 l + r$, $m_1 + n = (m'_1 + k - 1)l + r$, $m_2 + 1 = m'_2 l + r$, $m_2 + n = (m'_2 + k - 1)l + r$ for some $1 \leq r \leq l$ and

$$\omega_{m'_1 + 1} = \omega_{m'_1 + k} = \omega_{m'_2 + 1} = \omega_{m'_2 + k}.$$
Hence \( r = i + 1 = l - j \) and \( n = kl - j - i = (k - 1)l + 1 \). Lemma 3 implies that

\[
\gamma(R_\omega(m_1 + 1), R_\omega(m_1 + n)) = \gamma(R_\omega(m'_1 + 1), R_\omega(m'_1 + k))
\]

and

\[
\gamma(R_\omega(m_2 + 1), R_\omega(m_2 + n)) = \gamma(R_\omega(m'_2 + 1), R_\omega(m'_2 + k)).
\]

So

\[
\gamma(R_\omega(m'_1 + 1), R_\omega(m'_1 + k)) \neq \gamma(R_\omega(m'_2 + 1), R_\omega(m'_2 + k)).
\]

Since \( \pi(u, m_1) \sim \pi(u, m_2) \), all other relations between elements of \( \pi(u, m_1) \) are equal to those of \( \pi(u, m_2) \). If \( \omega_{m'_1 + t'} = \omega_{m'_1 + s'} \) for some \( 1 \leq t' < s' \leq k \), then it is clear that

\[
\gamma(R_\omega(m'_1 + t'), R_\omega(m'_1 + s')) = \gamma(R_\omega(m'_2 + t'), R_\omega(m'_2 + s')).
\]

By Lemma 3 the same equality holds when \( \omega_{m'_1 + t'} = \omega_{m'_1 + s'} \) for some \( 1 \leq t' < s' \leq k \) with \( t' \neq 1 \) or \( s' \neq k \). Since

\[
\gamma(R_\omega(m'_1 + 1), R_\omega(m'_1 + k)) \neq \gamma(R_\omega(m'_2 + 1), R_\omega(m'_2 + k)),
\]

we have proved that \( \pi(u', m'_1) \sim \pi(u', m'_2) \). Since \( \pi(u', m'_1) \neq \pi(u', m'_2) \) and \( \pi(u', m'_1) \sim \pi(u', m'_2) \), we obtain that

\[
\gamma(R_\omega(m'_1 + t'), R_\omega(m'_1 + s')) \neq \gamma(R_\omega(m'_2 + t'), R_\omega(m'_2 + s'))
\]

for some \( 1 \leq t' < s' \leq k \) with \( t' \neq 1 \) or \( s' \neq k \). Without loss of generality suppose that \( s' < k \): say \( R_\omega(m'_1 + t') < R_\omega(m'_1 + s') \) and \( R_\omega(m'_2 + t') > R_\omega(m'_2 + s') \). Since

\[
\omega_{m'_1 + t'} = u't' = \omega_{m'_2 + t'}
\]

and

\[
\omega_{m'_1 + s'} = u's' = \omega_{m'_2 + s'},
\]

we obtain \( \omega_{m'_1 + t'} = \omega_{m'_1 + s'} \) and \( \omega_{m'_1 + t'} = \omega_{m'_2 + s'} \).

Then Lemma 3 implies that \( R_\omega((m'_1 + t')l) < R_\omega((m'_1 + s')l) \) and \( R_\omega((m'_2 + t')l) > R_\omega((m'_2 + s')l) \). Since \( s'l < n \), we obtain that \( \omega_{(m'_1 + s')l} \) and \( \omega_{(m'_2 + s')l} \) are not the last symbols of the words \( \omega_{m_1 + 1} \ldots \omega_{m_1 + n} \) and \( \omega_{m_2 + 1} \ldots \omega_{m_2 + n} \), so \( \pi(u, m_1) \neq \pi(u, m_2) \) and \( \pi(u, m_1) \sim \pi(u, m_2) \).

4. Assume that

\[
\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) \neq \gamma(R_\omega(m_2 + t), R_\omega(m_2 + s))
\]

for some \( 1 \leq t < s \leq n \). Let us prove that \( t = 1 \) and \( s = n \). Lemma 3 implies that \( m_1 + t = (m'_1 + t' - 1)l + r, m_1 + s = (m'_1 + s' - 1)l + r, m_2 + t = (m'_2 + t' - 1)l + r, m_2 + s = (m'_2 + s' - 1)l + r \) for some \( 1 \leq r \leq l \) and

\[
\omega_{m'_1 + t'} = \omega_{m'_1 + s'} = \omega_{m'_2 + t'} = \omega_{m'_2 + s'}.
\]

Hence

\[
\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) = \gamma(R_\omega(m'_1 + t'), R_\omega(m'_1 + s'))
\]

and

\[
\gamma(R_\omega(m_2 + t), R_\omega(m_2 + s)) = \gamma(R_\omega(m'_2 + t'), R_\omega(m'_2 + s')).
\]
due to Lemma 4. So

$$\gamma(R_\omega(m_1^i + t'), R_\omega(m_1^i + s')) \neq \gamma(R_\omega(m_2' + t'), R_\omega(m_2' + s')).$$ 

Since $\pi(u, m_1^i) \sim \pi(u', m_2')$, we see that $t' = 1$ and $s' = k$. Hence $s - t = (s' - t')l = (k-1)l = n - 1$. So $t = 1$ and $s = n$.

Let us prove

$$\gamma(R_\omega(m_1 + 1), R_\omega(m_1 + n)) \neq \gamma(R_\omega(m_2 + 1), R_\omega(m_2 + n)).$$

Since $(u', m_1^i)$ is the ancestor of $(u, m_1)$, we obtain that $m_1 + 1 = m_1^i l + i + 1$ for some integer $i$. Analogously we obtain $m_2 + 1 = m_2' l + i + 1$. Since $n = (k-1)l + 1$, we have $m_1 + n = (m_1^i + k - 1)l + i + 1$ and $m_2 + n = (m_2' + k - 1)l + i + 1$ for the same $i$ by Remark 2 as $n \geq L_\omega$. Then Lemma 4 implies that

$$\gamma(R_\omega(m_1 + 1), R_\omega(m_1 + n)) = \gamma(R_\omega(m_1^i + 1), R_\omega(m_1^i + k))$$

and

$$\gamma(R_\omega(m_2 + t), R_\omega(m_2 + s)) = \gamma(R_\omega(m_2' + 1), R_\omega(m_2' + k)).$$

So

$$\gamma(R_\omega(m_1 + 1), R_\omega(m_1 + n)) \neq \gamma(R_\omega(m_2 + 1), R_\omega(m_2 + n)).$$

Thus $\pi(u, m_1) \sim (u, m_2)$.

5. Since $u$ has the interpretation $(u', i, j)$, $u$ is obtained from $\phi(u')$ by erasing $i$ symbols to the left and $j$ symbols to the right. So $|u| = |u'|l - i - j = kl - i - j$. Hence $0 \leq n + j - (k - 1)l - 1 < l$. Let

$$u_1 = \omega_{m_1 + n + 1} \ldots \omega_{m_1 + (k-1)l + 1}$$

and

$$u_2 = \omega_{m_2 + n + 1} \ldots \omega_{m_2 + (k-1)l + 1}$$

(since $n < (k - 1)l + 1$, the definition of words $u_1$ and $u_2$ is correct). Then words $uu_1$ and $uu_2$ are obtained from $\phi(u')$ by erasing $i$ symbols to the left and $n + j - (k - 1)l - 1$ symbols to the right. So $uu_1$ and $uu_2$ have the interpretation $(u', i, n + j - (k - 1)l - 1)$ and $u_1 = u_2$. Then $(u', m_1^i)$ and $(u', m_2')$ are the ancestors of occurrences $(uu_1, m_1)$ and $(uu_2, m_2)$. Since $|uu_1| = |uu_2| = (|u'| - 1)l + 1$, Case 4 of this Lemma implies that $\pi(uu_1, m_1) \sim (uu_2, m_2)$. Hence $\pi(uu_1, m_1)$ and $\pi(uu_2, m_2)$ differ only in relations of extreme elements and $\pi(u, m_1) = \pi(u, m_2)$.

6. Consider prefixes $u_1 = \omega_{m_1 + 1} \ldots \omega_{m_1 + (k-1)l + 1}$ and $u_2 = \omega_{m_2 + 1} \ldots \omega_{m_2 + (k-1)l + 1}$ of $u$. Since $u$ has the interpretation $(u', i, j)$, $u$ is obtained from $\phi(u')$ by erasing $i$ symbols to the left and $j$ symbols to the right. So $|u| = |u'|l - i - j = kl - i - j$. Hence $0 \leq n + j - (k - 1)l - 1 < l$. Then words $u_1$ and $u_2$ are obtained from $\phi(u')$ by erasing $i$ symbols to the left and $n + j - (k - 1)l - 1$ symbols to the right. So $u_1$ and $u_2$ have the interpretation $(u', i, n + j - (k - 1)l - 1)$. Then words $u_1$ and $u_2$ are the ancestors of occurrences $(u_1, m_1)$ and $(u_2, m_2)$. Since $|uu_1| = |uu_2| = (|u'| - 1)l + 1$, Case 4 of this Lemma implies that $\pi(uu_1, m_1) \sim (uu_2, m_2)$. Hence we have

$$\gamma(R_\omega(m_1 + 1), R_\omega(m_1 + (k - 1)l + 1)) \neq \gamma(R_\omega(m_2 + 1), R_\omega(m_2 + (k - 1)l + 1)).$$

Thus we prove that $\pi(u, m_1) \neq \pi(u, m_2)$. \qed
6 Algorithm for finding $f(u)$

Let $u$ be a subword of of length $n$ of $\omega$ and $n \geq L_\omega$. The number of permutations generated by $u$ is denoted by $f(u)$. In this section, we calculate $\sum_{|u|=n} f(u)$.

**Proposition 3** Let $\varphi \in Q_1$ and $\omega = \varphi(\omega)$. Then $L_\omega \leq l^2 + 1$.

**Proof:** Since $\varphi$ is a marked uniform morphism, it is sufficient to prove the uniqueness of the partition of the word $u$ with $|u| \geq l^2 + 1$ into blocks. Let word $u$ have two distinct partitions into blocks, that is $u = s_1 \varphi(x)p_1 = s_2 \varphi(y)p_2$, where $x$ and $y$ are some words, $s_1$ and $s_2$ are suffixes of $\varphi(a)$ and $\varphi(c)$ for $a,c \in \{0,1\}$, $p_1$ and $p_2$ are prefixes of $\varphi(b)$ and $\varphi(d)$ for $b,d \in \{0,1\}$. Let us prove that $|u| \leq l^2$. Let $x = x_1...x_t$ and $y = y_1...y_h$. Without loss of generality, we assume that $|s_2| < |s_1|$. Then $s_1 = s_2 eu$ for some word $u$ and letter $e$. Let $e = 0$ (the case when $e = 1$ is similar). Then $0u$ is a suffix of $\varphi(a)$ and $0u$ is a prefix of $\varphi(y_1)$. So $y_1 = 0$. Hence by Property 1 in the definition of $Q_1$ we have that $\varphi(0) = 0u1v$ for some word $v$. Then $\varphi(x_1) = 1v...$. So $x_1 = 1$. Hence by the Property 1 in the definition of $Q_1$ we have that $\varphi(1) = 1v0u'$. Then $\varphi(y_2) = 0...$ and $y_2 = 0$. So $\varphi(y_2) = 0u1v$. Hence $u' = u$ and $\varphi(1) = 1v0u$.

Continuing the procedure, we obtain that $a = x_1 = x_2 = ... = x_t = b = 1$. Then word $axb = 0t^2$ is a subword of $\omega$. By the definition of $Q_1$ we have that $0t^2$ and $1t^2+1$ are not subwords of $\omega$. So $t \leq l - 2$. Then $|u| = |s_1| + |p_1| + t \leq l^2$ ($|s_1| \leq t$ and $|p_1| \leq t$ since $s_1$ and $p_1$ are subwords of $\varphi(a)$ and $\varphi(b)$).

Thus we can take $L_\omega = l^2 + 1$. In what follows we assume that $L_\omega = l^2 + 1$. Let $n \geq L_\omega$. Then for $n$ there exists a unique pair of numbers $k(n)$ and $s(n)$ such that $s(n) > 0$, $k(n) \in \{1,...,l^2 - 1\}$ and $k(n) + (n) < n \leq (k(n) + 1)l^2(n)$. The number $n - k(n)l^2(n)$ is denoted by $r(n)$. We note that $n = k(n)l^2(n) + r(n)$ and $r(n) \in [1; l^2(n)]$.

For an arbitrary subword $u$ of the word $\omega$ we define the set $N_u$ of all pairs of conjugate permutations, and $M_u$ as the set of all remaining permutations generated by $u$ as subword of $\omega$. The set of all permutations generated by $u$ is denoted by $H_u$. We note that $|H_u| = f(u)$. The cardinality of the set $M_u$ is denoted by $m_u$, and the cardinality of the set $N_u$ is denoted by $n_u$. So we have $f(u) = m_u + 2n_u$.

Let $\mu(n) = \sum_{|u|=n} (m_u + n_u)$ and $\chi(n) = \sum_{|u|=n} f(u)$. The main theorem of this section follows:

**Theorem 1** Let $n \geq L_\omega$ and $\varphi \in Q_1$. Then

$$\sum_{|u|=n} f(u) = (r(n) - 1)\mu(k(n) + 2) + (l^2(n) - r(n) + 1)\chi(k(n) + 1).$$

Let $u$ be a subword of the word $\omega$ of length $n \geq L_\omega$, and $u'$ be the ancestor of $u$. Let $I_u$ be the set of integer such that for each $\pi \in H_u$ there exists a unique integer $m \in I_u$ such that $\pi = \pi(u, m)$. Now we define two important maps which will be used in what follows.

For each permutation $\pi$ of $H_u$, consider the occurrence $(u, m)$ such that $\pi = \pi(u, m)$ and $m \in I_u$ (and $m$ is uniquely defined due to the definition of $I_u$). Then we can define a map $\Psi_u : H_u \to H_{u'}$ by the rule $\Psi_u(\pi)(u') = \pi'(u,m')$, where $(u', m')$ is the ancestor of the occurrence $(u, m)$ and $\pi'(u', m')$.

For each permutation $\pi'$ of $H_{u'}$, consider the occurrence $(u', m')$ such that $\pi' = \pi(u', m')$ and $m' \in I_u$ (and $m'$ is uniquely defined due to the definition of $I_{u'}$). Then we can define a map $\Lambda_u : H_{u'} \to H_u$ by the rule $\Lambda_u(\pi') = \pi$, where $(u', m')$ is the ancestor of the occurrence $(u, m)$ and $\pi = \pi(u, m)$.

**Lemma 8** Let $u$ be a word of length $|u| = xl + r \geq L_\omega$ for $1 \leq r \leq l$, and $u'$ be the ancestor of $u$ of length $x + 2$. Then $f(u) = m_{u'} + n_{u'}$. 

Lemma 7. Since \( \pi \) elements of \( P \) the restriction of the map \( \Lambda \) permutations of \( M \).

Proof:\ Let us prove that \( m_{u'} + n_{u'} \leq |H_u| \). For any word \( v \) we define the set \( P_v \) which contains all permutations of \( M_v \) and one permutation of each pair of \( N_v \). It is clear that \( |P_v| = m_v + n_v \). Consider the restriction of the map \( \Lambda_u \) to the set \( P_{u'} \). Let \( \pi_1' = \pi(u', m_1') \) and \( \pi_2' = \pi(u', m_2') \) be two different elements of \( P_{u'} \). Then \( \pi_1' \sim \pi_2' \), since otherwise \( \pi_1', \pi_2' \in N_{u'} \) and it contradicts with the definition of \( P_{u'} \). Hence Case 3 of Lemma 7 implies that \( \Lambda_u(\pi_1') \neq \Lambda_u(\pi_2') \). Hence \( \Lambda_u \) is an injective map from \( P_{u'} \) to \( H_u \) and \( m_{u'} + n_{u'} = |P_{u'}| \leq |H_u| \).

Let us prove that \( |H_u| \leq m_{u'} + n_{u'} \). Consider the map \( \Psi_u : H_u \rightarrow H_u' \) defined above. Let \( \pi_1 = \pi(u, m_1) \) and \( \pi_2 = \pi(u, m_2) \) be two different elements of \( H_u \). Then \( \Psi_u(\pi_1) \neq \Psi_u(\pi_2) \) due to Case 1 of Lemma 7. Since \( (x + 1)l + 1 > xl + r \), we have that \( |u| < (|u'| - 1)l + 1 \). Then \( \Psi_u(\pi_1) \sim \Psi_u(\pi_2) \), since otherwise Case 3 of Lemma 7 would imply that \( \pi_1 = \pi_2 \). Thus we have proved that \( \Psi_u \) is an injective map and the image \( \Psi_u[H_u] \) of \( H_u \) does not contain conjugate permutations. Since the cardinality of any subset of \( H_u' \) which does not contain conjugate permutations is at most \( m_{u'} + n_{u'} \), we obtain that \( |H_u| \leq m_{u'} + n_{u'} \).

Combining the inequalities proven above, we obtain that

\[
f(u) = |H_u| = m_{u'} + n_{u'}.
\]

The lemma is proved. \( \square \)

Lemma 9. Let \( u \) be a word with \( |u| = xl + r \geq L_u \), \( u' \) be the ancestor of \( u \) and \( |u'| = x + 1 \). Then the following statements are true:

1. \( f(u) = f(u') \).
2. If \( r = 1 \), then \( m_u + n_u = m_{u'} + n_{u'} \).

Proof:\ 1. Consider the map \( \Psi_u : H_u \rightarrow H_u' \) defined above. Let \( \pi_1 = \pi(u, m_1) \) and \( \pi_2 = \pi(u, m_2) \) be two different elements of \( H_u \). Then \( \Psi_u(\pi_1) \neq \Psi_u(\pi_2) \) due to Case 1 of Lemma 7. Hence \( \Psi_u \) is an injective map and

\[
f(u) = |H_u| \leq |H_u'| = f(u')\]

Let us prove that \( f(u) \geq f(u') \). Consider the map \( \Lambda_u : H_u' \rightarrow H_u \) defined above. Let \( \pi_1' = \pi(u', m_1') \) and \( \pi_2' = \pi(u', m_2') \) be two different elements of \( H_u' \). Since \( xl + 1 \leq xl + r \), we have that \( |u| \geq (|u'| - 1)l + 1 \). If \( \pi_1' \sim \pi_2' \), then Case 3 of Lemma 7 implies that \( \Lambda_u(\pi_1') \neq \Lambda_u(\pi_2') \). If \( \pi_1' \sim \pi_2' \), then Cases 4 and 6 of Lemma 7 imply that \( \Lambda_u(\pi_1') \neq \Lambda_u(\pi_2') \). Hence \( \Lambda_u \) is an injective map and

\[
f(u') = |H_u'| \leq |H_u| = f(u).
\]

So \( f(u) = f(u') \).

2. Since \( r = 1 \), we have \( |u| = (|u'| - 1)l + 1 \). Let us prove that \( n_u \leq n_{u'} \). Consider a pair \( (\pi_1, \pi_2) \in N_u \). Then the pair \( (\Psi_u(\pi_1), \Psi_u(\pi_2)) \in N_{u'} \) due to Case 2 of Lemma 7. Moreover, two different pairs \( (\pi_1, \pi_2) \in N_u \) and \( (\pi_3, \pi_4) \in N_u \) correspond to two different pairs \( (\Psi_u(\pi_1), \Psi_u(\pi_2)) \) and \( (\Psi_u(\pi_3), \Psi_u(\pi_4)) \) due to Case 1 of Lemma 7. Hence \( n_u \leq n_{u'} \).

Let us prove that \( n_u \geq n_{u'} \). Consider a pair \( (\pi_1', \pi_2') \in N_{u'} \). Then the pair \( (\Lambda_u(\pi_1'), \Lambda_u(\pi_2')) \in N_u \) due to Case 3 of Lemma 7. Moreover, two different pairs \( (\pi_1', \pi_2') \in N_{u'} \) and \( (\pi_3', \pi_4') \in N_{u'} \) correspond to two different pairs \( (\Lambda_u(\pi_1'), \Lambda_u(\pi_2')) \) and \( (\Lambda_u(\pi_3'), \Lambda_u(\pi_4')) \) due to Case 3 of Lemma 7. Hence \( n_u \geq n_{u'} \).
Combining the inequalities proven above, we obtain that \( n_u = n_{u'} \). Moreover \( f(u) = f(u') \) due to Case 1 of this Lemma. So

\[
m_u + n_u = f(u) - n_u = f(u') - n_{u'} = m_{u'} + n_{u'}.
\]

\[\square\]

Recall that \( \varphi_{i;j}(v) \) is the word obtained from \( \varphi(v) \) by erasing \( i \) symbols to the left and \( j \) symbols to the right where \( 0 \leq i < l \) and \( 0 \leq j < l \). The set of all subwords of \( \omega \) of length \( n \) is denoted by \( F_\omega(n) \).

**Lemma 10** Let \( n = xl + r \geq L_\omega \), where \( 1 \leq r \leq l \). Then the following statements are true:

1. \( \chi(n) = (r - 1)\mu(x + 2) + (l - r + 1)\chi(x + 1) \).
2. \( \mu(n) = \chi(n) \) for \( r > 1 \) and \( \mu(xl + 1) = l\mu(x + 1) \).

**Proof:** Since \( n \geq L_\omega \), each word \( u \in F_\omega(n) \) has a unique interpretation \( \langle v, i, j \rangle \), where \( 0 \leq i < l \), \( 0 \leq j < l \) and \( v \) is the ancestor of \( u \). By the definition of interpretation we have \( |u| = |v|(l - i - j) \). Hence \( i + j \equiv l - r \) (mod \( l \)). So \( |v| = x + 2 \) with \( i + j = 2l - r \) or \( |v| = x + 1 \) with \( i + j = l - r \).

Let

\[
A_1 = \{ \varphi_{i;j}(v) | v \in F_\omega(x + 2), i + j = 2l - r \}
\]

and

\[
A_2 = \{ \varphi_{i;j}(v) | v \in F_\omega(x + 1), i + j = l - r \}.
\]

Let us prove the following assertion:

**Proposition 4**

1. \( F_\omega(n) = A_1 \cup A_2 \) and \( A_1 \cap A_2 = \emptyset \).
2. \( F_\omega(n) = A_2 \) for \( r = 1 \).

**Proof:** Let us prove that \( A_1 \cap A_2 = \emptyset \). Let \( u \in A_1 \cap A_2 \). Then \( u \) has interpretations with \( |v| = x + 2 \) and \( |v| = x + 1 \). So \( u \) has two different interpretations. It contradicts with \( |u| \geq L_\omega \). So \( A_1 \cap A_2 = \emptyset \).

Let us prove that \( A_1 \cup A_2 \subseteq F_\omega(n) \). Let \( v \) be a subword of \( \omega \). Since \( \omega \) is a fixed point of morphism \( \varphi \), \( \varphi(v) \) is a subword of \( \omega \). By the definition of \( \varphi_{i;j}(v) \) we have that \( \varphi_{i;j}(v) \) is a subword of \( \varphi(v) \). So \( \varphi_{i;j}(v) \) is a subword of \( \omega \). Let \( u \in A_1 \). Then \( u = \varphi_{i;j}(v) \) for some subword \( v \) of length \( x + 2 \) and \( i + j = 2l - r \).

Then

\[
|u| = |v|(l - i - j) = (x + 2)l - 2l + r = x + r.
\]

Since \( \varphi_{i;j}(v) \) is a subword of \( \omega \) and \( |u| = x + r = n \), we obtain that \( u \in F_\omega(n) \). Let \( u \in A_2 \). Then \( u = \varphi_{i;j}(v) \) for some subword \( v \) of length \( x + 1 \) and \( i + j = l - r \). Then

\[
|u| = |v|(l - i - j) = (x + 1)l - l + r = x + r.
\]

Since \( \varphi_{i;j}(v) \) is a subword of \( \omega \) and \( |u| = x + r = n \), we obtain that \( u \in F_\omega(n) \). Thus \( A_1 \cup A_2 \subseteq F_\omega(n) \).

Let us prove that \( F_\omega(n) = A_1 \cup A_2 \). Let \( u \in F_\omega(n) \). Then \( u \) has unique interpretation \( \langle v, i, j \rangle \), where \( 0 \leq i < l \), \( 0 \leq j < l \) and \( v \) is the ancestor of \( u \). Then \( u = \varphi_{i;j}(v) \) due to the definition of \( \varphi_{i;j}(v) \) and as we proved above \( |v| = x + 2 \) or \( |v| = x + 1 \). Hence \( u \in A_1 \) or \( u \in A_2 \). Thus \( F_\omega(n) \subseteq A_1 \cup A_2 \) and

\[
F_\omega(n) = A_1 \cup A_2.
\]
It remains to consider the case when $r = 1$. Since $0 \leq i < l$ and $0 \leq j < l$, we have $i + j < 2l - 1$. Then $A_1 = 0$ due to the definition of $A_1$. So $F_\omega(n) = A_2$ for $r = 1$ due to Case 1 of this Proposition. □

**Proof of Lemma 10**

1. We have $F_\omega(n) = A_1 \cup A_2$ due to Proposition 4 Then

$$\chi(n) = \sum_{|u| = n} f(u) = \sum_{u \in A_1} f(u) + \sum_{u \in A_2} f(u).$$

Let $u = \varphi_{i,j}(v) \in A_1$. Then $v$ is the ancestor of $u$, $|u| = n = xl + r$ and $|v| = x + 2$. Then Lemma 8 implies that $f(u) = m_v + n_v$. So

$$\sum_{u \in A_1} f(u) = \sum_{|v| = x + 2, i + j = 2l - r} f(\varphi_{i,j}(v)) = \sum_{|v| = x + 2} (r - 1)(m_v + n_v) = (r - 1) \sum_{|v| = x + 2} (m_v + n_v) = (r - 1)\mu(x + 2).$$

If $u = \varphi_{i,j}(v) \in A_2$, then $v$ is the ancestor of $u$, $|u| = n = xl + r$ and $|v| = x + 1$. Then Lemma 9 implies that $f(u) = f(v)$. So

$$\sum_{u \in A_2} f(u) = \sum_{|v| = x + 1, i + j = l - r} f(\varphi_{i,j}(v)) = \sum_{|v| = x + 1} (l - r + 1)f(v) = (l - r + 1)\sum_{|v| = x + 1} f(v) = (l - r + 1)\chi(x + 1).$$

Thus $\chi(n) = (r - 1)\mu(x + 2) + (l - r + 1)\chi(x + 1)$.

2. Let $r > 1$. Consider an arbitrary word $u$ of length $n$. Let $n_u > 0$. Then due to Case 2 of Lemma 7 the existence of two conjugate permutations $\pi(u, m_1)$ and $\pi(u, m_2)$ would imply that $|u| = (|u'| - 1)l + 1$, so that $n_u = 0$. Thus

$$\mu(n) = \sum_{|u| = n} (m_u + n_u) = \sum_{|u| = n} f(u) = \chi(n)$$

for $r > 1$.

Consider the case when $r = 1$. We have $F_\omega(n) = A_2$ by Proposition 4 Then

$$\mu(n) = \sum_{|u| = n} (m_u + n_u) = \sum_{u \in A_2} (m_u + n_u).$$

Let $u = \varphi_{i,j}(v) \in A_2$. Then $v$ is the ancestor of $u$, $|u| = n = xl + r$ and $|v| = x + 1$. Then Lemma 9 implies that $m_v + n_v = m_x + n_x$. So

$$\sum_{u \in A_2} (m_u + n_u) = \sum_{|v| = x + 1, i + j = l - 1} f(\varphi_{i,j}(v)) = \sum_{|v| = x + 1} l(m_v + n_v) = l \sum_{|v| = x + 1} (m_v + n_v) = l\mu(x + 1).$$

□

**Lemma 11** Let $n \geq L_\omega$. Then $\mu(n) = \chi(n)$ for $r(n) > 1$ and $\mu(n) = \mu(k(n) + 1)l^{r(n)}$ for $r(n) = 1$.

**Proof:** Let us prove by the induction on $s(n)$ that $\mu(n) = \chi(n)$ for $r(n) > 1$. For $s(n) = 1$ it is true due to Case 2 of Lemma 10. Let us prove the induction step. Let $n = xl + r_0$ for $r_0 \in [1, l]$. If $r_0 > 1$, then
Proof of Theorem 1: Consider the case when $r_0 = 1$. Then $n = xl + 1$ and we have $\mu(xl + 1) = l\mu(x + 1)$ due to Case 2 of Lemma 10. Since

$$k(n)l^{s(n)} + 2 \leq n \leq (k(n) + 1)l^{s(n)},$$

we have

$$k(n)l^{s(n)} - 1 + \frac{1}{l} \leq x \leq (k(n) + 1)l^{s(n)} - 1.$$

Hence

$$k(n)l^{s(n)} - 1 + 1 \leq x \leq (k(n) + 1)l^{s(n)} - 1.$$

So $x + 1 = k(n)l^{s(n)} - 1 + r'$ and $r' \in [2, l^{s(n)} - 1]$. Then by the induction assumption we have that $\mu(x + 1) = \chi(x + 1)$. Hence $\mu(xl + 1) = l\mu(x + 1) = l\chi(x + 1)$. Since $\chi(xl + 1) = l\chi(x + 1)$ due to Case 1 of Lemma 10, we obtain that $\mu(xl + 1) = \chi(xl + 1)$.

Let us prove the induction step. Let $s(n) = 1$. For $s(n) = 1$ it is true due to Case 2 of Lemma 10. Let us prove the induction step. We have $n = xl + 1$ for some $x$. Then $\mu(xl + 1) = l\mu(x + 1)$ due to Case 2 of Lemma 10. Moreover $x + 1 = k(n)l^{s(n)} - 1 + 1$. Then by the induction assumption we have that

$$\mu(x + 1) = \mu(k(n) + 1)l^{s(n)}.$$ 

Hence

$$\mu(n) = \mu(k(n) + 1)l^{s(n)}.$$ 

\[ \square \]

Proof of Theorem 1: Let us prove Theorem 1 by the induction on $s(n)$. For $s(n) = 1$ it is true due to Case 1 of Lemma 10. Let us prove the induction step. Let $n = xl + r_0$ for $r_0 \in [1, l]$. Since

$$k(n)l^{s(n)} + 1 \leq n \leq (k(n) + 1)l^{s(n)},$$

we have

$$k(n)l^{s(n)} - 1 + \frac{1 - l}{l} \leq x \leq (k(n) + 1)l^{s(n)} - 1.$$ 

Hence

$$k(n)l^{s(n)} - 1 \leq x \leq (k(n) + 1)l^{s(n)} - 1.$$ 

Since $x + 1 = \chi(n) + 1$, we have that $\mu(x + 2) = \chi(x + 2)$ due to Lemma 11. By Lemma 10 we have

$$\mu(n) = \mu(xl + 1) + l - r_0 + 1 \chi(x + 1).$$ 

Since $\mu(x + 2) = \chi(x + 2)$, we have that

$$\chi(n) = (r_0 - 1)\chi(x + 2) + (l - r_0 + 1)\chi(x + 1).$$ 

Therefore, $\mu(n) = \chi(n)$. 

\[ \square \]
By the induction assumption we have
\[ \chi(x + 2) = (x + 1 - k(n)l^{(n)-1})\mu(k(n) + 2) + ((k(n) + 1)l^{(n)-1} - x - 1)\chi(k(n) + 1) \]
and
\[ \chi(x + 1) = (x - k(n)l^{(n)-1})\mu(k(n) + 2) + ((k(n) + 1)l^{(n)-1} - x)\chi(k(n) + 1). \]
So \( \chi(n) = (r_0 - 1)\chi(x + 2) + (l - r_0 + 1)\chi(x + 1) = (xl + r_0 - k(n)l^{(n)} - 1)\mu(k(n) + 2) + ((k(n) + 1)l^{(n)} - xl + r_0 + 1)\chi(k(n) + 1) = (r(n) - 1)\mu(k + 2) + (l^{(n)} - r(n) + 1)\chi(k + 1). \)
It remains to consider the case when \( x + 2 = (k(n) + 1)l^{(n)-1} + 1. \) Then we have
\[ \mu(x + 2) = \mu(k(n) + 2)l^{(n)-1} \]
due to Lemma [11]. By the induction assumption we have
\[ \chi(x + 1) = (x - k(n)l^{(n)-1})\mu(k(n) + 2) + ((k(n) + 1)l^{(n)-1} - x)\chi(k(n) + 1). \]
Since \( x = (k(n) + 1)l^{(n)-1} - 1, \) we have
\[ \chi(x + 1) = (l^{(n)-1} - 1)\mu(k(n) + 2) + \chi(k(n) + 1). \]
So
\[ \chi(n) = (r_0 - 1)\mu(x + 2) + (l - r_0 + 1)\chi(x + 1) = (l^{(n)} - l + r_0 - 1)\mu(k(n) + 2) + (l - r_0 + 1)\chi(k(n) + 1). \]
Since \( r(n) = n - k(n)l^{(n)} = xl + r_0 - k(n)l^{(n)} = l^{(n)} - l + r_0, \) we have
\[ \chi(n) = (r(n) - 1)\mu((n)k + 2) + (l^{(n)} - r(n) + 1)\chi(k(n) + 1). \]

7 Special words

Recall that a subword \( v \) of the word \( \omega \) is called special (in \( \omega \)) if \( v0 \) and \( v1 \) are also subwords of \( \omega \). The set of all the special words of length \( n \) is denoted by \( B(n) \). Note that the unique interpretation of any special word \( v \) of length at least \( L_\omega \) is equal to \( \langle v', i, 0 \rangle \). Indeed, if \( j > 0 \), then \( v \) is uniquely completed to the right to a full block, and thus only one of the words \( v0 \) and \( v1 \) is a subword of \( \omega \).

Consider a special word \( v \). Let \( a \) be the first letter of \( v \) and \( b = \{0, 1 \} \setminus a \). Then \( vb \) cannot generate conjugate permutations. Let \( G_v = H_{va} \cap H_{vb} \). The cardinality of \( G_v \) is denoted by \( g(v) \). So \( g(v) \) is the number of common permutations generated by words \( v0 \) and \( v1 \). Let \( K_v \) be the set and \( k_v \) be the number of permutations of \( M_{va} \) which also belong to \( H_{vb} \). Let \( T_v \) be the set and \( t_v \) be the number of permutations of \( M_{va} \) each of which is conjugate to some permutation of \( H_{vb} \). Let \( R_v \) be the set and \( r_v \) be the number of permutations of \( H_{va} \setminus M_{va} \) which also belong to \( H_{vb} \). Thus if \( (\pi_1, \pi_2) \in N_v \) and \( \pi_1 \in R_v \), then \( \pi_2 \) is conjugate to some permutation of \( H_{vb} \).

Let \( \alpha(n) = \sum_{z \in B(n)} g(z) \) and \( \beta(n) = \sum_{z \in B(n)} (k_z + t_z + r_z) \).

The main theorem of this section is:
Theorem 2 Let \( n \geq L_\omega \) and \( \varphi \in Q_1 \). Then \( \sum_{v \in B(n)} g(v) = \beta(k(n) + 1) \) for \( r(n) < \nu(n) \) and \( \sum_{v \in B(n)} g(v) = \alpha(k(n) + 1) \) for \( r(n) = \nu(n) \).

To prove Theorem 2 we prove several auxiliary assertions. Consider the following Lemma (Lemma 1 from [Makarov 2006]).

Lemma 12 Let \( u = u_1 \ldots u_n \) and \( v = v_1 \ldots v_n \) be two subwords of any infinite binary word such that \( u_i \neq v_i \) for some \( 1 \leq i \leq n - 1 \). Then \( u \) and \( v \) do not generate equal permutations.

So, two words can generate equal permutations only if they are \( v_0 \) and \( v_1 \) for some special word \( v \). Since the sum \( \sum_{i=0} f(u) \) can be calculated as it is shown above, it remains to consider what happens with words \( v_0 \) and \( v_1 \) for all special words \( v \).

Lemma 13 Let \( (v_0, m_1) \) and \( (v_1, m_2) \) be some occurrences of words \( v_0 \) and \( v_1 \) with \( |v| = n \geq L_\omega \). \( (v'_0, m'_1) \) and \( (v'_1, m'_2) \) be the ancestors of occurrences of \( (v_0, m_1) \) and \( (v_1, m_2) \) with \( |v'| = k \), where \( \pi(v'_0, m'_1) = \pi(v'_1, m'_2) \). Then \( \pi(v_0, m_1) = \pi(v_1, m_2) \).

Proof: It is clear that \( (v'_0, m'_1) \) and \( (v'_1, m'_2) \) are the ancestors of occurrences \( (v, m_1) \) and \( (v, m_2) \). Note that \( \pi(v, m_1) = \pi(v, m_2) \) since otherwise \( \pi(v'_0, m'_1) \neq \pi(v'_0, m'_2) \) due to Case 1 of Lemma 7 and \( \pi(v'_0, m'_1) \neq \pi(v'_1, m'_2) \).

Consider \( 1 \leq t < n + 1 \) and the relations between the element number \( t \) and the last element of permutations \( \pi(v_0, m_1) \) and \( \pi(v_1, m_2) \). Lemma 5 implies that inequality\[
\gamma(R_\omega(m_1 + t), R_\omega(m_1 + n + 1)) \neq \gamma(R_\omega(m_2 + t), R_\omega(m_2 + n + 1))
\]
may hold only if\[
\gamma(R_\omega(m'_1 + t'), R_\omega(m'_1 + k + 1)) \neq \gamma(R_\omega(m'_2 + t'), R_\omega(m'_2 + k + 1))
\]
which is impossible since \( \pi(v'_0, m'_1) = \pi(v'_1, m'_2) \). Hence\[
\gamma(R_\omega(m_1 + t), R_\omega(m_1 + n + 1)) = \gamma(R_\omega(m_2 + t), R_\omega(m_2 + n + 1))
\]
for any \( 1 \leq t < n + 1 \). Thus we have proved that \( \pi(v_0, m_1) = \pi(v_1, m_2) \).

Lemma 14 Let \( (v_0, m_1) \) and \( (v_1, m_2) \) be some occurrences of words \( v_0 \) and \( v_1 \) with \( |v| = n \geq L_\omega \). \( (v'_0, m'_1) \) and \( (v'_1, m'_2) \) be the ancestors of \( (v_0, m_1) \) and \( (v_1, m_2) \) with \( |v'| = k \) where \( \pi(v'_0, m'_1) \neq \pi(v'_1, m'_2) \) and \( \pi(v'_0, m'_1) \sim \pi(v'_1, m'_2) \). Then \( \pi(v_0, m_1) \neq \pi(v_1, m_2) \) and \( \pi(v_0, m_1) \sim \pi(v_1, m_2) \).

Proof: Since \( v \) is a special word, we obtain that words \( v_0 \) and \( v_1 \) have the interpretations \( (v'_0, i, l - 1) \) and \( (v'_1, i, l - 1) \), where \( 0 \leq i < l \). Since \( \pi(v'_0, m'_1) \neq \pi(v'_1, m'_2) \) and \( \pi(v'_0, m'_1) \sim \pi(v'_1, m'_2) \), we obtain that two cases are possible.

In the first case\[
\gamma(R_\omega(m'_1 + t'), R_\omega(m'_1 + s')) \neq \gamma(R_\omega(m'_1 + s'), R_\omega(m'_1 + t'))
\]
for some \( 1 \leq t' < s' < k + 1 \). Then \( \pi(v'_0, m'_1) \neq \pi(v'_1, m'_2) \). If \( \pi(v'_0, m'_1) \sim \pi(v'_1, m'_2) \), then \( \pi(v_0, m_1) \neq \pi(v_1, m_2) \) due to Case 5 of Lemma 7. If \( \pi(v'_0, m'_1) \sim \pi(v'_1, m'_2) \), then \( \pi(v, m_1) \neq \pi(v, m_2) \) due to Case 4 of Lemma 7 since \( |v| \geq (|v'| - 1)l + 1 \). Hence \( \pi(v_0, m_1) \neq \pi(v_1, m_2) \) and \( \pi(v_0, m_1) \sim \pi(v_1, m_2) \).
In the second case
\[ \gamma(R_\omega(m'_1 + t'), R_\omega(m'_1 + k + 1)) \neq \gamma(R_\omega(m'_2 + t'), R_\omega(m'_2 + k + 1)) \]
for some \(1 < t' < k + 1\). Then Lemma 5 implies that
\[ \gamma(R_\omega((m'_1 + t' - 1)l + 1), R_\omega((m'_2 + k + 1)l + 1)) \neq \gamma(R_\omega((m'_2 + t' - 1)l + 1), R_\omega((m'_2 + k + 1)l + 1)). \]
Since \(t' > 1\), we obtain that the symbols \(\omega_{m'_1+1} \ldots \omega_{m'_1+m'_1+1} \) and \(\omega_{m'_2+1} \ldots \omega_{m'_2+m'_2+1} \) are not the first symbols of words \(\omega_{m_1+1} \ldots \omega_{m_1+n_1+1} \) and \(\omega_{m_2+1} \ldots \omega_{m_2+n_2+1} \). Thus we have proved that \(\pi(v, m_1) \neq \pi(v, m_2) \) and \(\pi(v, m_1) \bowtie \pi(v, m_2) \).

Lemma 15 Let \((v_0, m_1)\) and \((v_1, m_2)\) be some occurrences of words \(v_0\) and \(v_1\) with \(|v| = n \geq L_\omega\). \((v'_0, m'_1)\) and \((v'_1, m'_2)\) be the ancestors of \((v_0, m_1)\) and \((v_1, m_2)\) with \(|v'| = k\). Then the following statements are true:

1. If \(\pi(v'_0, m'_1) \sim \pi(v'_1, m'_2)\) and \(|v| = l|v'|\), then \(\pi(v, m_1) \sim \pi(v, m_2)\).
2. If \(\pi(v_0, m_1) \sim \pi(v_1, m_2)\), then \(\pi(v'_0, m'_1) \sim \pi(v'_1, m'_2)\) and \(|v| = l|v'|\).
3. If \(\pi(v'_0, m'_1) \sim \pi(v'_1, m'_2)\) and \(|v| < l|v'|\), then \(\pi(v, m_1) = \pi(v, m_2)\).

Proof: Since \(v\) is a special word, we obtain that words \(v_0\) and \(v_1\) have the interpretations \((v'_0, i, l - 1)\) and \((v'_1, i, l - 1)\), where \(0 \leq i < l\).

First let us prove the first and third statements. Since \(\pi(v'_0, m'_1) \sim \pi(v'_1, m'_2)\), by the definition of \(\sim\) we have that \(\pi(v'_0, m'_1) = \pi(v'_1, m'_2)\). It is clear that \((v'_0, m'_1)\) and \((v'_1, m'_2)\) are the ancestors of occurrences \((v, m_1)\) and \((v, m_2)\). Note that \(\pi(v, m_1) = \pi(v, m_2)\) since otherwise \(\pi(v'_0, m'_1) \neq \pi(v'_1, m'_2)\) due to Case 2 of Lemma 10.

Consider \(1 \leq t < n + 1\). Then Lemma 5 implies that either
\[ \gamma(R_\omega(m_1 + t), R_\omega(m_1 + n + 1)) = \gamma(R_\omega(m_2 + t), R_\omega(m_2 + n + 1)), \]
or \(m_1 + t = (m'_1 + t' - 1)l + 1, m_2 + t = (m'_2 + t' - 1)l + 1\) for some \(t'\) and
\[ \gamma(R_\omega(m'_1 + t'), R_\omega(m'_1 + k + 1)) \neq \gamma(R_\omega(m'_2 + t'), R_\omega(m'_2 + k + 1)). \]

Consider the second case. Then since \(\pi(v'_0, m'_1) \sim \pi(v'_1, m'_2)\), we have
\[ \gamma(R_\omega(m'_1 + t'), R_\omega(m'_1 + k + 1)) = \gamma(R_\omega(m'_2 + t'), R_\omega(m'_2 + k + 1)) \]
for \(1 < t' < k + 1\).

Consider the case of \(t' = 1\). Then \(m_1 + t = m'_1l + 1\) and \(m_2 + t = m'_2l + 1\). It is possible only if \(|v| = l|v'|\). So if \(|v| < l|v'|\), then \(\pi(v, m_1) = \pi(v, m_2)\). If \(|v| = l|v'|\), then
\[ \gamma(R_\omega(m_1 + t), R_\omega(m_1 + n + 1)) \neq \gamma(R_\omega(m_2 + t), R_\omega(m_2 + n + 1)) \]
due to Lemma 5 and \(\pi(v_0, m_1) \sim \pi(v_1, m_2)\).
On permutation complexity

Now let us prove the second statement. We have \( \pi(v_0, m_1) \sim \pi(v_1, m_2) \). Hence we obtain that
\[
\gamma(R_\omega(m'_1 i + l + 1), R_\omega((m'_1 + k) l + 1)) \neq \gamma(R_\omega(m'_2 i + l + 1), R_\omega((m'_2 + k) l + 1)).
\]
Lemma 5 implies that \( m'_1 i + l + 1 \equiv 1 \pmod{l} \) or \( m'_2 i + l + 1 \equiv 1 \pmod{l} \). Then \( i = 0 \) and \( n = kl \).

Since \( \pi(v_0, m_1) \sim \pi(v_1, m_2) \), we obtain \( \pi(v, m_1) = \pi(v, m_2) \). It is clear that \((v', m'_1)\) and \((v', m'_2)\) are the ancestors of occurrences \((v, m_1)\) and \((v, m_2)\). Since \( n = kl \), we have \(|v| > (|v'| - 1) l + 1 \). Hence \( \pi(v', m'_1) = \pi(v', m'_2) \) since otherwise either \( \pi(v, m_1) \neq \pi(v, m_2) \) due to Case 6 of Lemma 7 or \( \pi(v, m_1) \neq \pi(v, m_2) \) due to Case 6 of Lemma 7. Hence we obtain that
\[
\gamma(R_\omega(m'_1 i + t'), R_\omega(m'_1 s')) = \gamma(R_\omega(m'_2 + t'), R_\omega(m'_2 + s'))
\]
for \( 1 \leq t' < s' < k + 1 \).

It remains to consider the case \( s' = k + 1 \). Since \( \pi(v_0, m_1) \sim \pi(v_1, m_2) \), we have that \( \pi(v_0, m_1) \) and \( \pi(v_1, m_2) \) differ only in relations of extreme elements. Then Lemma 5 implies that
\[
\gamma(R_\omega(m'_1 i + t'), R_\omega((m'_1 + k) l + 1)) = \gamma(R_\omega(m'_2 + t'), R_\omega((m'_2 + k) l + 1))
\]
for \( 2 \leq t' < k + 1 \). In addition,
\[
\gamma(R_\omega(m_1 l + 1), R_\omega((m_1 + k) l + 1)) \neq \gamma(R_\omega(m_1 l + 1), R_\omega((m_1 + k) l + 1)).
\]
Hence Lemma 5 implies that
\[
\gamma(R_\omega(m'_1 + 1), R_\omega(m'_1 + k + 1)) \neq \gamma(R_\omega(m'_2 + t), R_\omega(m'_2 + k + 1)).
\]
Thus we have proved that \( \pi(v'0, m'_1) \sim \pi(v'1, m'_2) \) and \( n = kl \).

**Lemma 16** Let \( v \) be a special word with the ancestor \( v' \) with \(|v| \geq L_\omega \), and \(|v| < l |v'| \). Then \( g(v) = k_{v'} + t_{v'} + r_{v'} \).

**Proof:** Due to Case 5 of Lemma 15, the existence of two conjugate permutations \( \pi(v_0, m_1) \) and \( \pi(v_1, m_2) \) would imply that \(|v| = |v'| l \), so we have \( t_v = r_v = 0 \).

Let us prove that \( k_v \leq k_{v'} + t_{v'} + r_{v'} \). Let \( a \) be the first letter of \( v \) and \( b = \{0, 1\} \setminus a \). For each permutation \( \tau \) of \( K_v \), consider occurrences \((va, m_1)\) and \((vb, m_2)\) of words \( va \) and \( vb \) such that \( \tau = \pi(va, m_1) = \pi(vb, m_2) \). Then either \( \pi(v'a, m'_1) = \pi(v'b, m'_2) \), or \( \pi(v'a, m'_1) \sim \pi(v'b, m'_2) \) due to Lemma 14. If \( \pi(v'a, m'_1) = \pi(v'b, m'_2) \), then
\[
\Psi_{va}(\tau) = \tau' \in (M_{v'a} \cup H_{v'a} \setminus M_{v'a}) \cap H_{v'b} = K_v' \cup R_v'.
\]
If \( \pi(v'a, m'_1) \sim \pi(v'b, m'_2) \), then either \( \Psi_{va}(\tau) = \tau' \in T_v' \), or \( \Psi_{va}(\tau) = \tau' \sim \tau'' = \pi(v'a, m'_2) \) and \( \tau'' \in R_v' \). Let \( \tau_3 = \pi(va, m_3) \) and \( \tau_4 = \pi(va, m_4) \) be two different elements of \( K_v \). Then \( \Psi_{va}(\tau_3) \neq \Psi_{va}(\tau_4) \) due to Case 1 of Lemma 7 and \( \Psi_{va}(\tau_3) \sim \Psi_{va}(\tau_4) \) due to Case 5 of Lemma 7.
Hence \( \Psi_{va} \) is an injective map from \( K_v \) to \( H_{v'a} \) and \( \Psi_{va}[K_v] \) does not contain conjugate permutations. Hence
\[
k_v = |K_v| \leq k_{v'} + t_{v'} + r_{v'}.
\]
Let us prove that $k_v + t_v + r_v' \leq k_v$. Let $a$ be the first letter of $v'$ and $b = \{0, 1\} \setminus a$. For each permutation $\tau'$ of $K_v \cup T_v \cup R_v$, consider arbitrary occurrences $(v'a, m'_1)$ and $(v'b, m'_2)$ of words $v'a$ and $v'b$ such that $\tau' = \pi(v'a, m'_1)$ and either $\pi(v'a, m'_1) = \pi(v'b, m'_2)$, or $\pi(v'a, m'_1) \sim \pi(v'b, m'_2)$. Hence $\pi(va, m_1) = \pi(vb, m_2)$ due to Lemma 13 or Case 3 of Lemma 15. So $\Lambda_{va}(\tau') = \tau \in K_v$, or $\Lambda_{va}(\tau') = \tau \in R_v$. But we have already proved that $R_v = \emptyset$, so $\Lambda_{va}(\tau') \in K_v$. Let $\tau'_1$ and $\tau'_2$ be two different elements of $K_v \cup T_v \cup R_v'$. Then by the definition of $K_v, T_v$, and $R_v$ we have $\tau'_1 \sim \tau'_2$. Hence Case 3 of Lemma 7 implies that $\Lambda_{va}(\tau'_1) \neq \Lambda_{va}(\tau'_2)$. Hence $\Lambda_{va}$ is an injective map from $K_v \cup T_v \cup R_v'$ to $K_v$ and

$$k_v + t_v + r_v' = |K_v \cup T_v \cup R_v'| \leq |K_v| = k_v.$$ 

Combining the inequalities proven above, we obtain that $k_v = k_v' + t_v' + r_v'$. Since by definition $g(v) = k_v + r_v$, and as $r_v = 0$ we have $g(v) = k_v' + t_v' + r_v'$.

Lemma 17 Let $v$ be a special word with the ancestor $v'$ with $|v| \geq L_v$, and $|v' = l|v'|$. Then $g(v') = g(v)$.

Proof: Since $|v| = l|v'|$, we obtain that $v$ and $v'$ have the same first symbol $a$.

Let us prove $g(v') \leq g(v)$. For each permutation $\tau'$ of $G_v$, consider arbitrary occurrences $(v'a, m'_1)$ and $(v'b, m'_2)$ of words $v'a$ and $v'b$ such that $\tau' = \pi(v'a, m'_1) = \pi(v'b, m'_2)$. Let $\Lambda_{va}(\tau') = \tau$. By Lemma 13 we have $\pi(va, m_1) = \pi(vb, m_2)$. So $\tau \in G_v$. Let $\tau'_3$ and $\tau'_4$ be two different elements of $G_v$. Since $vb$ does not generate conjugate permutations, we have $\tau'_3 \sim \tau'_4$. Hence Case 3 of Lemma 7 implies that $\Lambda_{va}(\tau'_3) \neq \Lambda_{va}(\tau'_4)$. Hence $\Lambda_{va}$ is an injective map from $G_v$ to $G_v$ and

$$g(v') = |G_v| \leq |G_v'| = g(v).$$

Let us prove $g(v) \leq g(v')$. For each permutation $\tau$ of $G_v$, consider arbitrary occurrences $(va, m_1)$ and $(vb, m_2)$ of words $va$ and $vb$ such that $\tau = \pi(va, m_1) = \pi(vb, m_2)$. Let $\Psi_{va}(\tau) = \tau'$. Let us prove that $\tau' \in G_{v'}$. If $\pi(v'a, m'_1) \sim \pi(v'b, m'_2)$, then $\pi(va, m_1) \sim \pi(vb, m_2)$ due to Case 1 of Lemma 15. So $\pi(v'a, m'_1) = \pi(v'b, m'_2)$, or $\pi(v'a, m'_1) \sim \pi(v'b, m'_2)$ due to Lemma 14 and $\Psi_{va}(\tau) = \tau' \in G_{v'}$. Let $\tau_3$ and $\tau_4$ be two different elements of $G_v$. Hence Case 1 of Lemma 7 implies that $\Psi_{va}(\tau_3) \neq \Psi_{va}(\tau_4)$. Hence $\Psi_{va}$ is an injective map from $G_v$ to $G_{v'}$ and

$$g(v) = |G_v| \leq |G_{v'}| = g(v').$$

Lemma 18 Let $v$ be a special word with the ancestor $v'$ such that $|v| \geq L_\omega$, and $|v| = l|v'|$. Then $k_v + t_v + r_v = k_v' + t_v' + r_v'$.

Proof: Since $|v| = l|v'|$, we obtain that $v$ and $v'$ have the same first symbol $a$. Let $b = \{0, 1\} \setminus a$.

Let us prove that $t_v \leq t_v'$. For each permutation $\tau' \in T_{v'}$, consider arbitrary occurrences $(v'a, m'_1)$ and $(v'b, m'_2)$ of words $v'a$ and $v'b$ such that $\tau' = \pi(v'a, m'_1) \sim \pi(v'b, m'_2)$. Let $\Lambda_{va}(\tau') = \tau$. Let us prove that $\tau \in T_v$. Indeed, Case 1 of Lemma 15 implies that $\pi(va, m_1) \sim \pi(vb, m_2)$. Hence we have that either $\tau \in T_v$, or $\tau \sim \tau_1$, and $\tau_1 \in R_v$. Consider the second case. Then there exists an occurrence $(va, m_3)$ such that $\pi(va, m_3) \sim \pi(vb, m_3)$. Hence Case 2 of Lemma 7 implies that $\pi(v'a, m'_1) \sim \pi(v'a, m'_2)$. It contradicts with that $\tau' = \pi(v'a, m'_1) \in T_{v'}$. Let $\tau'_3$ and $\tau'_4$ be two different elements of $T_{v'}$. Then by
On permutation complexity

Let us prove that \( t_v \leq t_{v'} \). For each permutation \( \tau \) of \( T_v \), consider arbitrary occurrences \((va, m_1)\) and \((vb, m_2)\) of words \( va \) and \( vb \) such that \( \tau = \pi(va, m_1) \sim \pi(vb, m_2) \). Let \( \Psi_{va}(\tau) = \tau' \). Let us prove that \( \tau' \in T_{v'} \). Indeed, due to Case 2 of Lemma 15 we have \( \pi(v'a, m'_1) \sim \pi(v'b, m'_2) \). Hence we have either \( \Psi_{va}(\tau) = \tau' \in T_{v'} \), or \( \tau' \sim \tau'' \) and \( \tau'' \in R_{v'} \). Consider the second case. Then there exists an occurrence \((v'a, m'_1)\) such that \( \pi(v'a, m'_1) \sim \pi(v'b, m'_2) \). Hence Case 4 of Lemma 7 implies that \( \pi(va, m_1) \sim \pi(vb, m_3) \). It contradicts with \( \tau \in T_v \). Let \( \tau_3 \) and \( \tau_4 \) be two different elements of \( T_v \). Hence Case 1 of Lemma 7 implies that \( \Psi_{va}(\tau_3) \neq \Psi_{va}(\tau_4) \). Hence \( \Psi_{va} \) is an injective map from \( T_v \) to \( T_{v'} \)

\[
t_v = |T_v| \leq |T_{v'}| = t_{v'}.
\]

So \( t_v = t_{v'} \). By Lemma 17 we have \( g(v) = g(v') \). Since \( g(v) = k_v + r_v \) and \( g(v') = k_{v'} + r_{v'} \), we have

\[
k_v + t_v + r_v = k_{v'} + t_{v'} + r_{v'}.
\]

\[\square\]

**Lemma 19** Let \( n = x + r \geq L_\omega \), where \( 1 \leq r \leq l \). Then the following statements are true:

1. \( \alpha(n) = \beta(x + 1) \) for \( r \leq l \) and \( \alpha((x + 1)l) = \alpha(x + 1) \).

2. \( \beta(n) = \alpha(n) \) for \( r \leq l \) and \( \beta((x + 1)l) = \beta(x + 1) \).

**Proof:** Let \( u \in B(n) \). Since \( u \) is a special word with \( |u| \geq L_\omega \), \( u \) has unique interpretation \((v, i, 0)\), where \( 0 \leq i < l \) and \( v \) is the ancestor of \( u \). By the definition of interpretation we have \( |u| = |v|l - i \). Hence \( i \equiv l - r \) (mod \( l \)). So \( |v| = x + 1 \) and \( i = l - r \). \[\square\]

Let \( B_1 = \{ \varphi_{l-r,0}(v) | v \in B(x + 1) \} \). Let us prove the following assertion:

**Proposition 5** \( B(n) = B_1 \).

**Proof:** Let us prove that \( B_1 \subseteq B(n) \). Let \( v \in B(x + 1) \). Then \( v0 \) and \( v1 \) are subwords of \( \omega \). Since \( \omega \) is a fixed point of morphism \( \varphi \), \( \varphi(v0) \) and \( \varphi(v1) \) are subwords of \( \omega \). Since \( \varphi(v0) = \varphi(v)\varphi(0) = \varphi(v)0 \) and \( \varphi(v1) = \varphi(v)\varphi(1) = \varphi(v)1 \), words \( \varphi(v)0 \) and \( \varphi(v)1 \) are subwords of \( \omega \). By the definition of \( \varphi_{i,j}(v) \) we have that \( \varphi_{l-r,0}(v) \) is a suffix of \( \varphi(v) \). So \( \varphi_{l-r,0}(v0) \) and \( \varphi_{l-r,0}(v1) \) are subwords of \( \omega \). Let \( u = \varphi_{l-r,0}(v) \). Then

\[
|u| = |v|l - l + r = xl + r.
\]
Let $u$ of Lemma 15, the existence of two conjugate permutations $\pi \alpha$ Thus $118$

Proof of Lemma 19:

1. Let $r < l$. We have $B(n) = B_1$ due to Proposition 5 Then

$$\alpha(n) = \sum_{u \in B(n)} g(u) = \sum_{u \in B_1} g(u).$$

Let $u = \varphi_{l-r,0}(v) \in B_1$. Then $v$ is the ancestor of $u$, $|u| = n = xl + r$ and $|v| = x + 1$. Then Lemma 16 implies that $g(u) = k_v + t_v + r_v$. So

$$\sum_{u \in B_1} g(u) = \sum_{v \in B(x+1)} g(\varphi_{l-r,0}(v)) = \sum_{v \in B(x+1)} (k_v + t_v + r_v) = \beta(x + 1).$$

Thus $\alpha(n) = \beta(x + 1)$.

Let $r = l$. We have $B(n) = B_1$ due to Proposition 5 Then

$$\alpha(n) = \sum_{u \in B(n)} g(u) = \sum_{u \in B_1} g(u).$$

Let $u = \varphi_{0,0}(v) \in B_1$. Then $v$ is the ancestor of $u$, $|u| = n = (x + 1)l$ and $|v| = x + 1$. Then Lemma 17 implies that $g(u) = g(v)$. So

$$\sum_{u \in B_1} g(u) = \sum_{v \in B(x+1)} g(\varphi_{0,0}(v)) = \sum_{v \in B(x+1)} g(v) = \alpha(x + 1).$$

Thus $\alpha((x + 1)l) = \alpha(x + 1)$.

2. Let $r < l$. Consider an arbitrary special word $v$ of length $n$. Assume that $t_v > 0$. Then due to Case 2 of Lemma 15 the existence of two conjugate permutations $\pi(v0, m_1)$ and $\pi(v1, m_2)$ would imply that $|v| = |v'|/l$. It contradicts with $r < l$. So

$$\sum_{z \in B(n)} (k_z + t_z + r_z) = \sum_{z \in B(n)} (k_z + r_z) = \sum_{z \in B(n)} g(z).$$

Thus $\beta(n) = \alpha(n)$ for $r < l$.

Let $r = l$. We have $B(n) = B_1$ due to Proposition 5 Then

$$\beta(n) = \sum_{u \in B(n)} (k_u + t_u + r_u) = \sum_{u \in B_1} (k_u + t_u + r_u).$$
Let $u = \varphi_{100}(v) \in B_1$. Then $v$ is the ancestor of $u$, $|u| = n = (x+1)l$ and $|v| = x+1$. Then Lemma 18 implies that $k_u + t_u + r_u = k_v + t_v + r_v$. So

$$\sum_{u \in B_1} (k_u + t_u + r_u) = \sum_{v \in B(x+1)} (k_v + t_v + r_v) = (k(x+1) + 1) = \beta(x+1).$$

Thus $\beta((x+1)l) = \beta(x+1)$. \hfill \qed

**Lemma 20** Let $n \geq L_\omega$. Then $\beta(n) = \alpha(n)$ for $r(n) < l^s(n)$ and $\beta(n) = \beta(k(n)+1)$ for $r(n) = l^s(n)$.

**Proof:** Let us prove by the induction on $s(n)$ that $\beta(n) = \alpha(n)$ for $r(n) < l^s(n)$. For $s(n) = 1$ it is true due to Case 2 of Lemma 19. Let us prove the induction step. Let $n = xl + r_0$ for $r_0 \in [1,l]$. If $r_0 < l$, then $\beta(n) = \alpha(n)$ due to Case 2 of Lemma 19. Consider the case when $r_0 = l$. Then $n = (x+1)l$ and we have $\beta((x+1)l) = \beta(x+1)$ due to Case 2 of Lemma 19. Since $k(n)l^s(n) + 1 \leq n \leq (k(n)+1)l^s(n) - 1$, we have $x+1 \in [k(n)l^s(n)-1 + 1, (k(n)+1)l^s(n)-1]$. Then by the induction assumption we have that $\beta(x+1) = \alpha(x+1)$. Hence $\beta((x+1)l) = \alpha(x+1)$. Since $\alpha((x+1)l) = \alpha(x+1)$ due to Case 1 of Lemma 19, we obtain that $\beta((x+1)l) = \alpha((x+1)l)$.

Let us prove by the induction on $s(n)$ that $\beta((k(n)+1)l^s(n)) = \beta(k(n)+1)$. For $s(n) = 0$ it is true. Let us prove the induction step. We have $\beta(xl) = \beta(x)$ due to Case 2 of Lemma 19. By the induction assumption we have that $\beta((k(n)+1)l^{s(n)-1}) = \beta(k(n)+1)$. Hence $\beta((k(n)+1)l^s(n)) = \beta(k(n)+1).$ \hfill \qed

**Proof of Theorem 2:**

Let us prove that $\alpha((k(n)+1)l^s(n)) = \alpha(k(n)+1)$ by the induction on $s(n)$. For $s(n) = 1$ it is true due to Case 1 of Lemma 19. Let us prove the induction step. We have $\alpha((k(n)+1)l^{s(n)}) = \alpha((k(n)+1)l^{s(n)-1})$ due to Lemma 19. By the induction assumption we have $\alpha((k(n)+1)l^{s(n)-1}) = \alpha(k(n)+1)$. So

$$\alpha(n) = \alpha(k(n)+1)$$

for $r(n) = l^s(n)$.

Let us prove that $\alpha(n) = \beta(k(n)+1)$ for $r(n) < l^s(n)$. For $s(n) = 1$ it is true due to Case 1 of Lemma 19. Let us prove the induction step. Let $n = xl + r_0$ for $r_0 \in [1,l]$. Consider the case when $r_0 < l$. Since $k(n)l^{s(n)} + 1 \leq n \leq (k(n)+1)l^{s(n)} - 1$, we have

$$k(n)l^{s(n)-1} + \frac{1-l}{l} \leq x \leq (k(n)+1)l^{s(n)-1} - \frac{2}{l}.$$

Hence

$$k(n)l^{s(n)-1} \leq x \leq (k(n)+1)l^{s(n)-1} - 1.$$
Hence $x+1 \in [k(n)t^{s(n)}-1, (k(n) + 1)t^{s(n)}-1]$. If $x+1 \in [k(n)t^{s(n)}-1, (k(n) + 1)t^{s(n)}-1]$, then $\beta(x+1) = \alpha(x+1)$ due to Lemma 20. Hence $\alpha(n) = \alpha(x+1)$. By the induction assumption we have $\alpha(x+1) = \beta(k(n) + 1)$. Hence $\alpha(n) = \beta(k(n) + 1)$. It remains to consider the case when $x+1 = (k(n) + 1)t^{s(n)}-1$. Then we have $\beta(x+1) = \beta(k(n) + 1)$ due to Lemma 20. Hence $\alpha(n) = \beta(x+1) = \beta(k(n) + 1)$.

Consider the case when $r_0 = l$. Then $n = (x+1)/l$ and we have $\alpha(n) = \alpha(x+1)$ due to Lemma 19. Since

$$k(n)t^{s(n)}-1 \leq n \leq (k(n) + 1)t^{s(n)} - 1,$$

we have

$$k(n)t^{s(n)}-1 \leq x+1 \leq (k(n) + 1)t^{s(n)} - 1.$$  

Then $\alpha(n) = \beta(k(n) + 1)$ due to the induction assumption. So $\alpha(n) = \beta(k(n) + 1)$. 

\[\square\]

8 Computing the permutation complexity

In this section we state the main theorem of this article. Let $n \geq L_\omega$. Then for $n$ there exists a unique pair of numbers $k(n)$ and $s(n)$ such that

$$s(n) > 0, k(n) \in \{l, \ldots, l^2 - 1\}$$

and

$$k(n)t^{s(n)} < n \leq (k(n) + 1)t^{s(n)}.$$  

The number $n - k(n)t^{s(n)}$ is denoted by $r(n)$. We note that $n = k(n)t^{s(n)} + r(n)$ and $r(n) \in [1; t^{s(n)}]$. Recall that $\mu(n) = \sum_{|u|=n}(m_u + n_u)$, $\chi(n) = \sum_{|u|=n} f(u)$, $\alpha(n) = \sum_{z \in B(n)} g(z)$ and $\beta(n) = \sum_{z \in B(n)} (k_z + t_z + r_z)$.

Theorem 3 Let $\omega$ be a fixed point of the morphism $\varphi$, where $\varphi \in Q_\ell$ and $n \geq L_\omega$. Then the permutation complexity of $\omega$ is calculated as follows:

$$\lambda(n) = (r(n) - 1)\mu(k(n) + 2) + (t^{s(n)} - r(n) + 1)\chi(k(n) + 1) - \beta(k(n) + 1)$$

for $r(n) > 1$ and

$$\lambda(n) = t^{s(n)}\chi(k(n) + 1) - \alpha(k(n))$$

for $r(n) = 1$.

Proof: We note that $\sum_{|u|=n} f(u)$ is the number of permutations, each of them is generated by at least one occurrence of some subword of word $\omega$ of length $n$. It is clear that some permutations can be calculated several times. But Lemma 12 implies that two distinct subwords $u_1$ and $u_2$ of word $\omega$ can generate the same permutations if and only if $u_1 = v0$ and $u_2 = v1$ up to a relabeling of $u_1$ and $u_2$. Hence only $g(v)$ permutations are calculated two times in the sum $\sum_{|u|=n} f(u)$. Thus

$$\lambda(n) = \sum_{|u|=n} f(u) - \sum_{b \in B(n-1)} g(b).$$

Combining Theorem 1 and 2 we prove the main theorem.
Now for the calculation of $\lambda(n)$ it remains to compute $\mu(k(n) + 2)$, $\chi(k(n) + 1)$, $\beta(k(n) + 1)$ and $\alpha(k(n))$ for $k(n) \in \{1, \ldots, l^2 - 1\}$. Thus it is sufficient to find the set $H_u$(the set of permutations generated by $u$) for any subword $u$ of $\omega$ with $|u| \in \{l + 1, \ldots, l^2 + 1\}$.

**Proposition 6** Let $\varphi \in Q_1$ and $\omega = \varphi(\omega)$. Then $\omega$ is $l^2 + 1$–free.

**Proof:** Let us prove that $v^{l^2 + 1}$ is not subword of $\omega$ by the induction on $|v|$. If $|v| = 1$, then $v$ is some letter, i.e., $a^{l^2 + 1}$ is the subword of $\omega$ for some $a \in \{0, 1\}$. Since $l^2 + 1 > 2l - 1$, we have that $\varphi(b)$ is the subword $a^{l^2 + 1}$ for some $b \in \{0, 1\}$. Hence $\varphi(b) = a^l$ and we obtain contradiction (otherwise Properties in the definition of $Q_l$ do not hold).

Let us prove the induction step. Assume that $u^{l^2 + 1}$ is a subword of $\omega$. Let $v_1 = v_2 = \ldots = v_{l^2 + 1} = v$. Since $|v| \geq 2$ and $2l^2 \geq l^2 + 1$, we obtain that words $v_1v_2 \ldots v_{l^2 + 1}$ and $v_2v_3 \ldots v_{l^2 + 1}$ have the same partitions into blocks. From this partitions we have that $v_1 = s_1 \varphi(x)s_2$, where $x$ is a some word, $s_1$ is the suffix of $\varphi(a)$ and $s_2$ is the prefix of $\varphi(b)$ for $a, b \in \{0, 1\}$. Since $v_1v_2 \ldots v_{l^2 + 1}$ and $v_2v_3 \ldots v_{l^2 + 1}$ have the same partitions into blocks, we have that $v_2 = s_1 \varphi(x)s_2$. Moreover $s_2s_1 = \varphi(c)$ for some $c \in \{0, 1\}$. Continuing the procedure, we obtain that

$$v_1 = v_2 = \ldots = v_{l^2 + 1} = s_1 \varphi(x)s_2.$$  

So

$$v^{l^2 + 1} = v_1 \ldots v_{l^2 + 1} = s_1 \varphi(x)s_2s_1 \varphi(x)s_2 \ldots s_1 \varphi(x)s_2$$

is the subword of $\omega$. Then $(cx)^{l^2 + 1}$ also is the subword of $\omega$. Since $|cx| < |v|$, we obtain a contradiction. \hfill $\Box$

We find $H_u$ by Algorithm 1:

**Algorithm 1.**

1. We consider all occurrences $(u, m)$ of word $u$ in word $\varphi^5(0)$.
2. Let $1 \leq i < j \leq |u|$. Since $\omega$ is $l^2 + 1$–free, we have that words $\omega_{m+i} \ldots \omega_{m+i+(j-i)l^2-1}$ and $\omega_{m+j} \ldots \omega_{m+j+(j-i)l^2-1}$ are distinct. Let

$$u_i = \omega_{m+i} \ldots \omega_{m+i+(|u|-1)l^2-1}$$

and

$$u_j = \omega_{m+j} \ldots \omega_{m+j+(|u|-1)l^2-1}.$$  

Then $u_i \neq u_j$. Since

$$R_{\omega}(m+i) = 0, u_i,$$

and

$$R_{\omega}(m+j) = 0, u_j,$$

we obtain that $R_{\omega}(m+i) > R_{\omega}(m+j)$ if and only if $u_i > u_j$ due to Proposition 2. So if we know word

$$\omega_{m+1} \ldots \omega_{m+(|u|-1)(l^2+1)},$$

then we can find relation $\gamma(R_{\omega}(m+i), R_{\omega}(m+j))$. Thus we find permutation $\pi(u, m)$.  

Proposition 7 Let \((u, m_1)\) and \((u, m_2)\) be some occurrences of \(u\) such that \(m_1 \equiv m_2 \pmod{l}\), \((u', m'_1)\) and \((u', m'_2)\) be ancestors of \((u, m_1)\) and \((u, m_2)\). Then if \(\pi(u', m'_1) = \pi(u', m'_2)\), then \(\pi(u, m_1) = \pi(u, m_2)\).

Proof: Consider relations \(\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s))\) and \(\gamma(R_\omega(m_2 + t), R_\omega(m_2 + s))\) for \(1 \leq t < s \leq |u|\). If \(\omega_{m_1 + t} \neq \omega_{m_1 + s}\), then \(\omega_{m_2 + t} \neq \omega_{m_2 + s}\). Hence

\[
\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) = \gamma(\omega_{m_1 + t}, \omega_{m_1 + s})
\]

and

\[
\gamma(R_\omega(m_2 + t), R_\omega(m_2 + s)) = \gamma(\omega_{m_2 + t}, \omega_{m_2 + s})
\]

So

\[
\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) = \gamma(R_\omega(m_2 + t), R_\omega(m_2 + s))
\]

Consider the case when \(\omega_{m_1 + t} = \omega_{m_1 + s}\) and \(\omega_{m_2 + t} = \omega_{m_2 + s}\). Let \(u_1 = \omega_{m_1 + 1} \ldots \omega_{m_1 + n}\) and \(u_2 = \omega_{m_2 + 1} \ldots \omega_{m_2 + n}\). Since \((u', m'_1)\) and \((u', m'_2)\) are ancestors of \((u, m_1)\) and \((u, m_2)\) and \(m_1 \equiv m_2 \pmod{l}\), words \(u_1\) and \(u_2\) have the same partitions in the correct partition of \(\omega\). Hence \(\omega_{m_1 + t}, \omega_{m_2 + s}\), \(\omega_{m_1 + s}\) lie in blocks \(\varphi(\omega_{m'_1 + s'}, \omega_{m'_2 + s'})\) and \(\varphi(\omega_{m'_1 + s'})\) in the correct partition of \(\omega\) for some \(1 \leq t' < s' \leq |u'|\). Moreover \(\omega_{m_1 + t'} = \omega_{m'_1 + t'}\) and \(\omega_{m_1 + s'} = \omega_{m'_1 + s'}\). Let

\[
\omega_{m'_1 + t'} = \omega_{m'_2 + t'} = a
\]

and

\[
\omega_{m'_1 + s'} = \omega_{m'_2 + s'} = b.
\]

Since \(m_1 \equiv m_2 \pmod{l}\), we have \(m_1 + t \equiv m_2 + t \pmod{l}\) and \(m_1 + s \equiv m_2 + s \pmod{l}\). Applying Lemma 2 to \((u, m_1)\) and \((u, m_2)\), we obtain that

\[
\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) = \gamma(R_\omega(m_2 + t), R_\omega(m_2 + s))
\]

in the case when \(a \neq b\) or \(s \neq t \pmod{l}\). In the case when \(a = b\) and \(s \equiv t \pmod{l}\) we have

\[
\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) = \gamma(R_\omega(m'_1 + t'), R_\omega(m'_1 + s'))
\]

and

\[
\gamma(R_\omega(m_2 + t), R_\omega(m_2 + s)) = \gamma(R_\omega(m'_2 + t'), R_\omega(m'_2 + s')).
\]

Since \(\pi(u', m'_1) = \pi(u', m'_2)\), we have

\[
\gamma(R_\omega(m_1 + t), R_\omega(m_1 + s)) = \gamma(R_\omega(m_2 + t), R_\omega(m_2 + s))
\]

and \(\pi(u, m_1) = \pi(u, m_2)\).

Lemma 21

1. Let \((u, m_1)\) and \((u, m_2)\) be two occurrences of \(u\) of length at most 2. Then \(\pi(u, m_1) = \pi(u, m_2)\).

2. \(\varphi^3(0)\) contains all subwords of word \(\omega\) of length 2.
On permutation complexity

3. Let \( \pi \in H_\omega \) and \( |u| \leq l + 1 \). Then there exists an occurrence \((u, m)\) of \( u\) such that \( \pi(u, m) = \pi \) and \((u, m)\) is an occurrence of \( u \) in \( \varphi^i(0) \).

4. Let \( \pi \in H_\omega \) and \( |u| \in \{l + 1, \ldots, l^2 + 1\} \). Then there exists an occurrence \((u, m)\) of \( u \) such that \( \pi(u, m) = \pi \) and \((u, m)\) is an occurrence of \( u \) in \( \varphi^i(0) \).

Proof:
1. The case when \( |u| = 1 \) is an obvious because \( \pi(u, m) = 1 \) for any occurrence \((u, m)\). Consider the case when \( |u| = 2 \). Let \( u = ab \). If \( a \neq b \), then \( \gamma(R(m + 1), R(m + 2)) = \gamma(a, b) \) for any occurrence \((u, m)\). Thus we have \( \pi(u, m_1) = \pi(u, m_2) \) for \( a \neq b \).

   Consider the case when \( a = b \). Let \( a = 0 \) (the case when \( a = 1 \) is similar). Let us prove that \( \gamma(R(m + 1), R(m + 2)) = \gamma(0, 0^t-m-1 \ldots 0, 0^t-m-2 \ldots) = < \).

2. Since \( \varphi \in Q_t \), we have that \( \varphi \) is a marked morphism and \( \varphi(0) \) starts with 0. Since \( \varphi \) is a marked morphism, \( \varphi(1) \) starts with 1. Let \( \varphi(0) = 0^k1 \ldots \) for \( k > 1 \) or \( \varphi(0) = 0^1 \). If \( \varphi(0) = 0^k1 \ldots \) then \( 0u1 \) is a subword of \( \varphi(0) \) and \( 0u0 \) is a prefix of \( \varphi(0) \) for empty word \( u \). It contradicts with Property 1 in the definition of \( Q_t \). If \( \varphi(0) = 0^1 \), then \( 0u1 \) is a suffix of \( \varphi(0) \) and \( 0u0 \) is a prefix of \( \varphi(0) \) for empty word \( u \). It contradicts with Property 1 in the definition of \( Q_t \). Thus \( \varphi(0) \) starts with 01. Analogously one can obtain that \( \varphi(1) \) starts with 10. Since 01 is a subword of \( \varphi(0) \) and \( \varphi(01) \) is a subword of \( \varphi^2(0) \). But we have

\[
\varphi(01) = \varphi(0)\varphi(1) = 01\ldots 10...
\]

So 01 and 10 are subwords of \( \varphi^2(0) \). Let \( \varphi(0) = 0xa \) and \( \varphi(1) = 1yb \) for some words \( x, y \) and letters \( a \) and \( b \). Since \( \varphi \) is a marked morphism, \( a \neq b \). Consider the case when \( a = 1 \) and \( b = 0 \). Then

\[
\varphi(01) = \varphi(0)\varphi(1) = \ldots 11...
\]

and

\[
\varphi(10) = \varphi(0)\varphi(1) = \ldots 00,....
\]

So 00 and 11 are subwords of \( \varphi^3(0) \).

It remains to consider the case when \( a = 0 \) and \( b = 1 \). Let word \( aa \) be a subword of \( \omega \). Let \( i \) be the minimal number such that \( \omega_i\omega_{i+1} = aa \). Let \( u = \omega_i\omega_{i+1} \). If \( u \) lies in block \( \varphi(c) \) for some \( c \in \{0, 1\} \) in the correct partition of \( \omega \) into blocks, then \( u \) is a subword of \( \varphi(c) \). Then \( \varphi^2(c) = \varphi(c) \ldots \) and \( u \) is a subword of \( \varphi^2(c) \). Since \( c \) is a subword of \( \varphi(0) \), \( u \) is a subword of \( \varphi^3(0) \). It remains the case when \( \omega_1 \) and \( \omega_{i+1} \) lie in blocks \( \varphi(\omega_j) \) and \( \varphi(\omega_{j+1}) \) in the correct partition of \( \omega \) into blocks. Then \( \varphi(\omega_j) \) ends with \( a \) and \( \varphi(\omega_{j+1}) \) starts with \( a \). Hence \( \omega_j = \omega_{j+1} = a \). So \( \omega_j\omega_{j+1} = aa \) and \( j < i \). It contradicts with the minimality of \( i \). Thus if \( aa \) is a subword of \( \omega \), then \( aa \) is a subword of \( \varphi^3(0) \).

3. Let \( |u| = k \). Since \( \pi \in H_\omega \), there exists some occurrence \((u, m_1)\) of \( u \) such that \( \pi(u, m_1) = \pi \). Let \( (u'_{m_1}, m'_1) \) be the ancestor of \((u, m_1)\). Since \( |u| \leq l + 1 \), we have that either \( \omega_{m_1+1} \ldots \omega_{m_1+k} = sp \), where \( s \) is a suffix of \( \varphi(\omega_i) \), \( p \) is a prefix of \( \varphi(\omega_{i+1}) \) for some \( i \), or \( \omega_{m_1+1} \ldots \omega_{m_1+k} \) is a subword of \( \varphi(\omega_i) \) for some \( i \). Consider the first case. Then \( m_1 = il - |s| \). Let \( \omega_i = a \) and \( \omega_{i+1} = b \). Then
$u'_m = ab$ due to the definition of the ancestor of occurrence. Since $\varphi^3(0)$ contain all subwords of word $\omega$ of length 2, there exists $m'$ such that $\omega_{m'+1}\omega_{m'+2} = ab$ and $\omega_{m'+1}\omega_{m'+2}$ is a subword of $\varphi^3(0)$. Since $\omega = \varphi(\omega)$, we have $\omega_{(m'+1)l-|s|} \cdots \omega_{(m'+1)l-|s|+k-1} = sp$. Thus $(ab, m')$ is the ancestor of $(u, m)$ due to the definition of the ancestor of occurrence, where $m = (m' + 1)l - |s|$. Moreover $m \equiv m_1 \pmod{l}$. We have $\pi(ab, m') = \pi(ab, m'_1)$ due to Case 1 of this lemma. Since $m \equiv m_1 \pmod{l}$, Proposition 7 implies that $\pi(u, m) = \pi(u, m_1)$. The case when $\omega_{m_1} \cdots \omega_{m_1+k}$ is a subword of $\varphi(\omega_i)$ for some $i$ is similar. Since $(u'_m, m')$ is an occurrence of $u'_m$ in $\varphi^3(0)$, $(u, m)$ is an occurrence of $u$ in $\varphi^4(0)$.

4. Since $\pi \in H_u$, there exists some occurrence $(u, m_1)$ of $u$ such that $\pi(u, m_1) = \pi$. Let $(u'_m, m'_1)$ be the ancestor of $(u, m_1)$. Since $|u| \leq l^2 + 1$, we have that $|u'_m| \leq l + 1$. Then there exists an occurrence $(u'_m, m')$ of $u'_m$ in $\varphi^4(0)$ such that $\pi(u'_m, m') = \pi(u'_m, m'_1)$ due to Case 3 of this Lemma. Let $m = m'l + r$, where $r$ is the residue of $m_1$ modulo $l$. Since $\omega = \varphi(\omega)$, we have $\omega_{m'l + r} \cdots \omega_{m'l + r + |u| - 1} = u$. Thus $(u'_m, m')$ is the ancestor of $(u, m)$ due to the definition of the ancestor of occurrence. Then Proposition 7 implies that $\pi(u, m) = \pi(u, m_1)$. Since $(u'_m, m')$ is an occurrence of $u'_m$ in $\varphi^4(0)$, $(u, m)$ is an occurrence of $u$ in $\varphi^5(0)$. □

The correctness of Algorithm 1. By Lemma 21 we have that for any permutation $\pi$ from the set $H_u$ there exists an occurrence $(u, m)$ of word $u$ such that $\pi = \pi(u, m)$ and $\omega_{m+1}\omega_{m+2} \cdots \omega_{m+|u|}$ is a subword of $\varphi^3(0)$. Thus Algorithm 1 is correct.

9 Permutation complexity of the Thue-Morse Word

Widmer (2011) calculated the factor complexity of the permutation generated by the Thue-Morse word. In this section, we present an alternative proof for his formula. Recall that Thue-Morse word is a fixed point $\omega = \varphi(\omega)$ of morphism $\varphi(0) = 01, \varphi(1) = 10$. In what follows in this section $\omega$ is the Thue-Morse word.

As we note in previous section for the calculation of $\lambda(n)$ it is sufficient to find the set $H_u$ for any subword $u$ of $\omega$ with $|u| \in \{l + 1, \ldots, l^2 + 1\}$. Since for Thue-Morse word $l = 2$, it is sufficient to find the set $H_u$ for any subword $u$ of $\omega$ with $|u| \in \{3, 4, 5\}$. It can be found by Algorithm 1. We consider in detail Algorithm 1 for words 010 and 01100. We consider word

$$\varphi^5(0) = 01101001100110100011001011001.$$  

An word 0010 has two occurrences in $\varphi^5(0)$. It is (010, 3) and (010, 10). Now we find $\pi(010, 3)$ and $\pi(010, 10)$.

Permutation $\pi(010, 3)$.

We have $\omega_{10} = 100110010$. Hence $R_{\omega}(4) = 0, 0100110010 \ldots$, $R_{\omega}(5) = 0, 100110010 \ldots$ and $R_{\omega}(6) = 0, 01010010 \ldots$. So $R_{\omega}(4) < R_{\omega}(4) < R_{\omega}(5)$. Thus $\pi(010, 3) = 231$.

Permutation $\pi(010, 10)$.

We have $\omega_{10} = 1001101001$. Hence $R_{\omega}(10) = 0, 0101101001 \ldots$, $R_{\omega}(12) = 0, 10110101 \ldots$ and $R_{\omega}(13) = 0, 01100101 \ldots$. So $R_{\omega}(10) < R_{\omega}(14) < R_{\omega}(13)$. So $\pi(010, 10) = 132$.

An word 01100 has two occurrences in $\varphi^5(0)$. It is (01100, 6) and (01100, 20). Now we find $\pi(01100, 6)$ and $\pi(01100, 20)$.

Alexandr Valyuzhenich
On permutation complexity

Permutation $π(01100, 6)$. We have $ω_7...ω_{20} = 0110010111010111001$. Hence $R_ω(7) = 0, 0110010111010111001\ldots, R_ω(8) = 0, 110010111010111001\ldots, R_ω(9) = 0, 01011011101111001\ldots, R_ω(10) = 0, 010110101101101\ldots$ and $R_ω(11) = 0, 010110101101101\ldots$. So $π(01100, 6) = 35412$.

Permutation $π(01100, 20)$. We have $ω_{21}...ω_{40} = 0110011011001100110110110$. Hence $R_ω(21) = 0, 0110011011001100110110110\ldots, R_ω(22) = 0, 110011011001100110110\ldots, R_ω(23) = 0, 01011011001100110110110\ldots, R_ω(24) = 0, 011011001100110110110\ldots$ and $R_ω(25) = 0, 011011001100110110110\ldots$. So $π(01100, 20) = 25413$.

Thus we obtain that $H_{01100} = \{25413, 35412\}$.

For other subwords $u$ of $ω$ with $|u| \in \{3, 4, 5\}$ we analogously find $H_u$ by the Algorithm 1.

Subpermutations of length 3.

$F_ω(3) = \{001, 010, 011, 100, 101, 110\}$. We have $H_{001} = \{123\}, H_{010} = \{132, 231\}, H_{011} = \{132\}, H_{100} = \{312\}, H_{101} = \{213, 312\}$ and $H_{110} = \{321\}$. Thus $χ(3) = \sum_{|u|=3} f(u) = \sum_{|u|=3} |H_u| = 8$.

We have $B_ω(2) = \{01, 10\}$. Since $H_{010} = \{132, 231\}$ and $H_{011} = \{132\}$, we have $g(01) = 1$. Since $H_{100} = \{312\}$ and $H_{101} = \{213, 312\}$, we have $g(10) = 1$. So

$$α(2) = \sum_{v \in B(2)} g(v) = 2.$$

Subpermutations of length 4.

$F_ω(4) = \{0101, 0110, 1001, 1010, 1011, 1100, 1101, 0010, 0011, 0100\}$. We have $H_{0101} = \{1324\}, H_{0110} = \{2431\}, H_{1001} = \{3124\}, H_{1010} = \{4231\}, H_{1011} = \{3142\}, H_{1100} = \{4312\}, H_{1101} = \{3412\}, H_{0010} = \{1243\}, H_{0011} = \{1243\}$ and $H_{0100} = \{2413\}$. Hence $m_u = 1$ and $n_u = 0$ for arbitrary subword $u$ of $ω$ of length 4. So

$$μ(4) = \sum_{|u|=4} (m_u + n_u) = 10$$

and

$$χ(4) = \sum_{|u|=4} f(u) = 10.$$

We have $B_ω(3) = \{001, 010, 101, 110\}$. Since $H_{0010} = \{1243\}$ and $H_{0011} = \{1243\}$, we have $g(001) = k_{001} = 1$ and $t_{001} = r_{001} = 0$. Since $H_{0100} = \{2413\}$ and $H_{0101} = \{1324\}$, we have $g(010) = k_{010} = t_{010} = r_{010} = 0$. Since $H_{1010} = \{4231\}$ and $H_{1011} = \{3142\}$, we have $g(101) = k_{101} = t_{101} = r_{101} = 0$. Since $H_{1100} = \{4312\}$ and $H_{1101} = \{3412\}$, we have $g(110) = k_{110} = 1$ and $t_{110} = r_{110} = 0$. So

$$α(3) = \sum_{v \in B(3)} g(v) = 2$$

and

$$β(3) = \sum_{v \in B(3)} (k_v + t_v + r_v) = 2.$$
Subpermutations of length 5.
\( F_ω(5) = \{01011, 10110, 01100, 11001, 01101, 11010, 10010, 00101, 10011, 01010, 10100, 01001\}. \)

We have \( H_{01011} = \{14253\}, H_{10110} = \{42531\}, H_{01100} = \{25413, 35412\}, H_{11001} = \{43125, 53124\}, H_{01101} = \{25413\}, H_{11010} = \{54321\}, H_{10010} = \{41253\}, H_{00101} = \{12435\}, H_{10011} = \{31254, 41253\}, H_{00110} = \{13542, 23541\}, H_{10100} = \{52413\} \) and \( H_{11001} = \{24135\}. \) Hence \( m_{01100} = m_{10011} = 0, n_{01100} = n_{10011} = 1 \) and \( m_u = 1, n_u = 0 \) for other subwords \( u \) of \( ω \) of length 5. So
\[
μ(5) = \sum_{|u|=5} (m_u + n_u) = 12.
\]

We have \( B_ω(4) = \{0110, 1001\}. \) Since \( H_{01100} = \{25413, 35412\} \) and \( H_{01101} = \{25413\}, \) we have \( k_{0110} = t_{0110} = 0 \) and \( r_{0110} = 1. \) Since \( H_{10010} = \{41253\} \) and \( H_{10011} = \{31254, 41253\}, \) we have \( k_{1001} = t_{1001} = 0 \) and \( r_{1001} = 1. \) So
\[
β(4) = \sum_{v \in B(4)} (k_v + t_v + r_v) = 2.
\]

Thus if \( n \geq 5 \) and \( n \in [2^{s+1} + 1, 3 \cdot 2^s], \) then \( k(n) = 2, s(n) = s \) and we have
\[
λ(n) = (r(n) - 1)μ(4) + (2^s - r(n) + 1)χ(3) - β(3)
\]
for \( r > 1 \) and
\[
λ(n) = 2^sχ(3) - α(2)
\]
for \( r = 1 \) due to Theorem 3. So in this case
\[
λ(n) = 10(r(n) - 1) + 8(2^s - r(n) + 1) - 2 = 2(2^{s+2} + r(n) - 2)
\]
for \( r(n) > 1 \) and
\[
λ(n) = 8 \cdot 2^s - 2 = 2(2^{s+2} - 1)
\]
for \( r(n) = 1. \)

For \( 3 \cdot 2^s + 1 \leq n \leq 2^{s+2} \) we have \( k(n) = 3, s(n) = s \) and Theorem 3 implies that
\[
λ(n) = (r(n) - 1)μ(5) + (2^s - r(n) + 1)χ(4) - β(4)
\]
for \( r > 1 \) and
\[
λ(n) = 2^sχ(4) - α(3)
\]
for \( r(n) = 1. \) So in this case
\[
λ(n) = 12(r(n) - 1) + 10(2^s - r(n) + 1) - 2 = 2(2^{s+2} + (2^s + r(n)) - 2)
\]
for \( r(n) > 1 \) and
\[
λ(n) = 10 \cdot 2^s - 2 = 2(2^{s+2} + 2^s - 1)
\]
for \( r(n) = 1. \)

Thus the formula for the permutation complexity of the Thue-Morse word is
\[
λ(n) = \sum_{|u|=n} f(u) - \sum_{b \in B(n-1)} g(b) = 2^{k+2} + 2b - 2 = 2(2^{k+1} + b - 2)
\]
for \( n = 2^k + b \geq 6, \) where \( 0 < b \leq 2^k. \)
10 Concluding remark

In this section we describe marked \( l \)-uniform binary morphisms for which we can apply our approach and calculate the permutation complexity of their fixed points. We note that Lemma 1 and Lemma 2 are key for our approach. Actually, if a marked \( l \)-uniform morphism satisfies Lemma 1 and Lemma 2, then we can calculate the permutation complexity of its fixed point. So to apply our method we need that the morphism satisfies Lemma 1 and Lemma 2. Let us prove that for all marked \( l \)-uniform morphisms Lemma 1 holds only if it belongs to the class \( Q_l \).

Let \( \varphi \) be a marked \( l \)-uniform morphisms. Let us prove that if \( \varphi \not\in Q_l \), then Lemma 1 does not hold for \( \varphi \). Recall that the partition of \( \omega \) into blocks which are the images of its symbols is called correct.

Suppose that the first property in the definition of \( Q_l \) does not hold for \( \varphi \). There are two cases. In the first case \( \varphi(0) = 0u0x \) for some word \( x \) and \( 0u1 \) is a subword of \( \varphi(0) \) or \( \varphi(1) \). Let \( 0u1 \) be a subword of \( \varphi(a) \), where \( a \in \{0, 1\} \). Then \( \varphi(a) = z0u1y \) for some word \( z \) and \( y \). It is clear that the correct partition of \( \omega \) contains at least one block \( \varphi(a) \). Let \( \omega_j \) lie in block \( \varphi(a) \) in the correct partition of \( \omega \) and \( j \equiv |z| + 1 \pmod{l} \). Then \( R_{\omega_j}(j) = 0, 0u1y \ldots \). Moreover we have \( j \not\equiv 1 \pmod{l} \). It is clear that the correct partition of \( \omega \) contains at least one block \( \varphi(0) \). Let \( \omega_i \) lie in block \( \varphi(0) \) in the correct partition of \( \omega \) and \( i \equiv 1 \pmod{l} \). Then \( R_{\omega_i}(i) = 0, 0u0 \ldots \) Then

\[
\gamma(R_{\omega}(i), R_{\omega}(j)) = \gamma(0, 0u0 \ldots, 0, 0u1 \ldots) = <
\]

and Lemma 1 does not hold for morphism \( \varphi \).

In the second case \( \varphi(0) = 0u0x \) for some word \( x \) and \( 0u \) is a suffix of \( \varphi(0) \) or \( \varphi(1) \). Let \( 0u \) be a suffix of \( \varphi(b) \), where \( b \in \{0, 1\} \). Then \( \varphi(b) = z0u \) for some word \( z \). Let \( \omega_j \) lie in block \( \varphi(b) \) which is followed by \( \varphi(c) \) for some \( c \in \{0, 1\} \) in the correct partition of \( \omega \) and \( j \equiv |z| + 1 \pmod{l} \). Then \( R_{\omega_i}(j) = 0, 0uc \ldots \). Moreover we have \( j \not\equiv 1 \pmod{l} \). Let \( \omega_i \) lie in block \( \varphi(0) \) in the correct partition of \( \omega \) and \( i \equiv 1 \pmod{l} \). Then \( R_{\omega}(i) = 0, 0u0 \ldots \) Then

\[
\gamma(R_{\omega}(i), R_{\omega}(j)) = \gamma(R_{\omega}(i + |u| + 1), R_{\omega}(j + |u| + 1)).
\]

If \( c = 1 \), then \( \gamma(R_{\omega}(i + |u| + 1), R_{\omega}(j + |u| + 1)) = < \) and Lemma 1 does not hold for morphism \( \varphi \). If \( c = 0 \), then inequalities \( R_{\omega}(i + |u| + 1) < R_{\omega}(j + |u| + 1) \) and \( R_{\omega}(i) > R_{\omega}(j) \) do not hold simultaneously. So Lemma 1 does not hold for \( R_{\omega}(i) \) and \( R_{\omega}(j) \) or \( R_{\omega}(i + |u| + 1) \) and \( R_{\omega}(j + |u| + 1) \). The case when the second property in the definition of \( Q_l \) does not hold for \( \varphi \) is similar.

Thus in a sense class \( Q_l \) is optimal in the class of marked \( l \)-uniform morphisms for our approach.
