A graph $G$ is a 2-tree if $G = K_3$, or $G$ has a vertex $v$ of degree 2, whose neighbors are adjacent, and $G - v$ is a 2-tree. Clearly, if $G$ is a 2-tree on $n$ vertices, then $|E(G)| = 2n - 3$. A non-increasing sequence $\pi = (d_1, \ldots, d_n)$ of nonnegative integers is a graphic sequence if it is realizable by a simple graph $G$ on $n$ vertices. Yin and Li (Acta Mathematica Sinica, English Series, 25(2009)795–802) proved that if $k \geq 2$, $n \geq \frac{2}{3} k^2 + \frac{19}{2} k$ and $\pi = (d_1, \ldots, d_n)$ is a graphic sequence with $\sum_{i=1}^{n} d_i > (k - 2)n$, then $\pi$ has a realization containing every tree on $k$ vertices as a subgraph. Moreover, the lower bound $(k - 2)n$ is the best possible. This is a variation of a conjecture due to Erdős and Sós. In this paper, we investigate an analogue extremal problem for 2-trees and prove that if $k \geq 3$, $n \geq \frac{2}{3} k^2 - k$ and $\pi = (d_1, \ldots, d_n)$ is a graphic sequence with $\sum_{i=1}^{n} d_i > \frac{4kn}{3} - \frac{5n}{3}$, then $\pi$ has a realization containing every 2-tree on $k$ vertices as a subgraph. We also show that the lower bound $\frac{4kn}{3} - \frac{5n}{3}$ is almost the best possible.

Keywords: degree sequences; graphic sequences; realization; 2-trees.

1 Introduction

Let $K_m$ be the complete graph on $m$ vertices. A graph $G$ is a 2-tree if $G = K_3$, or $G$ has a vertex $v$ of degree 2, whose neighbors are adjacent, and $G - v$ is a 2-tree. It is easy to see that if $G$ is a 2-tree on $n$ vertices, then $|E(G)| = 2n - 3$. An ear in a 2-tree is a vertex of degree 2 whose neighbors are adjacent.

The set of all non-increasing sequences $\pi = (d_1, \ldots, d_n)$ of nonnegative integers with $d_1 \leq n - 1$ is denoted by $NS_n$. A sequence $\pi \in NS_n$ is said to be graphic if it is the degree sequence of a simple graph $G$ on $n$ vertices, and such a graph $G$ is called a realization of $\pi$. The set of all graphic sequences in $NS_n$ is denoted by $GS_n$. For a nonnegative integer sequence $\pi = (d_1, \ldots, d_n)$, we denote $\sigma(\pi) = d_1 + \cdots + d_n$. Yin and Li \textsuperscript{12} investigated a variation of a conjecture due to Erdős and Sós (see \textsuperscript{1}, Problem 12 in page 247), that is, an extremal problem for a sequence $\pi \in GS_n$ to have a realization containing every tree on $k$ vertices as a subgraph, and obtained the following Theorem 1.1.

Theorem 2.1 ([12]) If \( k \geq 2 \), \( n \geq \frac{2}{3}k^2 + \frac{19}{2}k \) and \( \pi = (d_1, \ldots, d_n) \in GS_n \) with \( \sigma(\pi) > (k - 2)n \), then \( \pi \) has a realization \( H \) containing every tree on \( k \) vertices as a subgraph. Moreover, the lower bound \((k - 2)n\) is the best possible.

This kind of extremal problem was firstly introduced by Erdős et al. (see [5–6]). The purpose of this paper is to investigate an analogous extremal problem for a sequence \( \pi \in GS_n \) to have a realization containing every 2-tree on \( k \) vertices as a subgraph. We establish the following Theorems 1.2 and 1.3.

Theorem 1.2 If \( k \geq 3 \), \( n \geq 2k^2 - k \) and \( \pi = (d_1, \ldots, d_n) \in GS_n \) with \( \sigma(\pi) > \frac{4kn}{3} - \frac{5n}{3} \), then \( \pi \) has a realization \( H \) containing every 2-tree on \( k \) vertices as a subgraph.

The lower bound \( \frac{4kn}{3} - \frac{5n}{3} \) in Theorem 1.2 is almost the best possible.

Theorem 1.3 For \( k = i(\text{mod } 3) \), there exists a sequence \( \pi \in GS_n \) with \( \sigma(\pi) = 2\lfloor \frac{2k}{3} \rfloor n - 2n - \lfloor \frac{2k}{3} \rfloor^2 + \lfloor \frac{2k}{3} \rfloor + 1 - (-1)^i \) such that \( \pi \) has no realization containing every 2-tree on \( k \) vertices.

2 Proof of Theorem 1.2

In order to prove Theorem 1.2, we need some known results. Let \( \pi = (d_1, \ldots, d_n) \in NS_n \) and \( k \) be an integer with \( 1 \leq k \leq n \). Let

\[
\pi^* = \begin{cases} 
(d_1 - 1, \ldots, d_{k-1} - 1, d_{k+1} - 1, \ldots, d_{d_k+1} - 1, d_{d_k+2}, \ldots, d_n), & \text{if } d_k \geq k, \\
(d_1 - 1, \ldots, d_{d_k} - 1, d_{d_k+1}, d_{d_k+2}, \ldots, d_n), & \text{if } d_k < k.
\end{cases}
\]

Let \( \pi^*_k = (d'_1, \ldots, d'_{n-1}) \), where \( d'_1 \geq \cdots \geq d'_{n-1} \) is a rearrangement in non-increasing order of the \( n - 1 \) terms of \( \pi^*_k \). We say that \( \pi^*_k \) is the residual sequence obtained from \( \pi \) by laying off \( d_k \). It is easy to see that if \( \pi^*_k \) is graphic then so is \( \pi \), since a realization \( G \) of \( \pi \) can be obtained from a realization \( G' \) of \( \pi^*_k \) by adding a new vertex of degree \( d_k \) and joining it to the vertices whose degrees are reduced by one in going from \( \pi \) to \( \pi^*_k \). In fact, more is true:

Theorem 2.1 ([7]) \( \pi \in GS_n \) if and only if \( \pi^*_k \in GS_{n-1} \).

Theorem 2.2 ([4]) Let \( \pi = (d_1, \ldots, d_n) \in NS_n \), where \( \sigma(\pi) \) is even. Then \( \pi \in GS_n \) if and only if \( \sum_{i=1}^{n} d_i \leq t(t-1) + \sum_{i=t+1}^{n} \min\{t, d_i\} \) for any \( t \) with \( 1 \leq t \leq n-1 \).

Theorem 2.3 ([11]) Let \( \pi = (d_1, \ldots, d_n) \in NS_n \), where \( d_1 = m \) and \( \sigma(\pi) \) is even. If there exist an integer \( n_1 \leq n \) and some integer \( h \geq 1 \) such that \( d_{n_1} \geq h \) and \( n_1 \geq \frac{1}{4} \left[ \frac{(m+h+1)^2}{4} \right] \), then \( \pi \in GS_n \).

Theorem 2.4 ([6]) If \( \pi = (d_1, \ldots, d_n) \in NS_n \), has a realization \( G \) containing \( H \) as a subgraph, then there exists a realization \( G' \) of \( \pi \) containing \( H \) as a subgraph so that the vertices of \( H \) have the largest degrees of \( \pi \).

Theorem 2.5 ([10]) Let \( n \geq r \) and \( \pi = (d_1, \ldots, d_n) \in GS_n \) with \( d_r \geq r - 1 \). If \( d_i \geq 2r - 2 - i \) for \( i = 1, \ldots, r - 2 \), then \( \pi \) has a realization containing \( K_r \).

Theorem 2.6 ([9]) If \( r \geq 1 \), \( n \geq 2r - 1 \) and \( \pi = (d_1, \ldots, d_n) \in GS_n \) with \( \sigma(\pi) \geq 2n(r-2) + 2 \), then \( \pi \) has a realization containing \( K_r \).
An extremal problem of graphic sequences with a realization containing every 2-tree with given size

**Theorem 2.7** Let \( \pi = (d_1, \ldots, d_n) \in GS_n. \)

1. If \( n \geq 6 \) and \( \sigma(\pi) \geq 2n \), then \( \pi \) has a realization containing \( K_3. \)
2. If \( n \geq 7 \) and \( \sigma(\pi) \geq 3n - 1 \), then \( \pi \) has a realization containing \( K_4 - e \), where \( K_4 - e \) is the graph obtained from \( K_4 \) by removing one edge.
3. If \( n \geq 9 \) and \( \sigma(\pi) \geq 5n - 6 \), then \( \pi \) has a realization containing \( K_5 - e \), where \( K_5 - e \) is the graph obtained from \( K_5 \) by removing one edge.

We note that a 2-tree can be constructed from an edge by repeatedly adding a new vertex and making it adjacent to the two ends of an edge in the graph formed so far. We refer to the initial edge in constructing such a 2-tree as a base of the 2-tree. Some properties of 2-trees can be summarized as follows.

**Theorem 2.8** Let \( G \) be a 2-tree with \( n \geq 3 \) vertices. Then

1. \( G \) has at least two ears,
2. Every vertex of degree 2 in \( G \) is an ear,
3. No two ears in \( G \) are adjacent unless \( G = K_3, \)
4. Every edge of \( G \) can be a base.

We know that \( G \) is a 2-tree if either \( G = K_3 \), or \( G \) has an ear \( u \) such that \( G' = G - u \) is a 2-tree. In other words, every 2-tree \( G \neq K_3 \) can be obtained from some 2-tree \( G' \) by adding a new vertex \( u \) adjacent to two vertices, \( v \) and \( w \), where \( vw \in E(G') \). We call this process attaching \( u \) to \( vw \) and denote \( vw = e(u) \).

For a 2-tree \( G \), we denote \( B(G) \) to be the set of all ears in \( G \) and \( C(G) = \{ e(u) | u \in B(G) \} \). For \( xy \in C(G) \), we denote \( B(xy) = \{ u | u \in B(G) \text{ and } e(u) = xy \} \). Denote \( T(k) = K_2 + K_{k-2} \) (a star in \( 2 \)-trees), where \( K_{k-2} \) is the complement of \( K_{k-2} \) and \( + \) denotes ‘join’. Clearly, \( T(k) \) is a 2-tree with \( k \) vertices and \( k - 2 \) ears, and every ear attaches to the edge of \( K_2 \). We also need the following lemmas.

**Lemma 2.1** Let \( G \) be a 2-tree on \( k \geq 6 \) vertices and \( G \neq T(k) \). Then \( |C(G)| \geq 2. \)

**Proof:** If \( |C(G)| = 1 \), let \( C(G) = \{ xy \} \), then \( u \) attaches to \( xy \) for each \( u \in B(G) \). Let \( G' = G \setminus B(G) \). Since \( G \neq T(k) \), we have that \( |V(G')| \geq 3 \), \( G' \) is a 2-tree and each vertex of \( V(G') \setminus \{ x, y \} \) has degree at least 3 in \( G' \). This implies that \( G' \neq K_3 \), and \( x \) and \( y \) are exactly two ears in \( G' \) by Theorem 2.8(1). This is impossible by Theorem 2.8(3).

**Lemma 2.2** Let \( G \) be a 2-tree on \( k \geq 6 \) vertices. Let \( xy \in C(G) \) so that \( xy \) is attached to as few ears as possible, and let \( s \) be the number of these ears. Denote \( H = G \setminus (B(xy) \cup \{ x, y \}) \). Then \( H \) is a spanning subgraph of some 2-tree on \( k - s - 2 \) vertices.

**Proof:** Clearly, Lemma 2.2 is trivial for \( G = T(k) \). Assume \( G \neq T(k) \). Let \( G' = G \setminus B(xy) \), where \( |B(xy)| = s \). Then \( G' \) is a 2-tree on \( k - s \) vertices. If \( s = 1 \), then by \( k \geq 6, \) we have \( k - s \geq 5 \). If \( s \geq 2 \), then by \( |C(G)| \geq 2 \) (Lemma 2.1) and the minimality of \( s \), we have \( k - s \geq (s + 1) + 2 \geq 5 \).

By Theorem 2.8(4), \( G' \) can be constructed from \( xy \) by repeatedly adding a new vertex and making it adjacent to the two ends of an edge in the graph formed so far. In the process of constructing \( G' \) from \( xy \), we let \( y' \) be the first vertex that is attached to \( xy \). Since \( xy \) can not be attached to an ear in \( G' \), we have that \( d_{G'}(y') \geq 3 \). This implies that \( xy' \) or \( yy' \) must be attached to a new vertex. Let \( x' \) be the first vertex that is attached to \( xy' \) or \( yy' \). Without loss of generality, we assume that \( x' \) is attached to \( xy' \). Let
\{x_1, \ldots, x_t\} be the subset of \(V(G')\) so that \(x_i\) is attached to \(xx'\) for \(i = 1, \ldots, t\) and \(\{y_1, \ldots, y_t'\}\) be the subset of \(V(G'')\) so that \(y_j\) is attached to \(yy'\) for \(j = 1, \ldots, t'\). Denote
\[
G'' = G' - \{xx_1, \ldots, xx_t\} - \{yy_1, \ldots, yy_{t'}\} + \{y'y_1, \ldots, y'y_{t'}\} + \{x'x_1, \ldots, x'x_t\} - \{xy, xy'\}.
\]
In \(G''\), we first delete edges \(xx'\) and \(yy'\), and then identify the vertex \(x\) to the vertex \(x'\) and identify the vertex \(y\) to the vertex \(y'\), the resulting graph is denoted by \(G''\). Then \(G''\) is a simple graph and is a 2-tree on \(k-s-2\) vertices. Moreover, \(H = G \setminus (B(xy) \cup \{x, y\}) = G' \setminus \{x, y\}\) is a spanning subgraph of \(G''\).

\[\square\]

**Lemma 2.3** Let \(k \geq 6, n \geq k\) and \(\pi = (d_1, \ldots, d_n) \in GS_n\) with \(\sigma(\pi) > \frac{4kn}{3} - \frac{5n}{3}\). Then \(d_i \geq k - \left\lceil \frac{r^2}{2} \right\rceil\) for \(i = 1, \ldots, \left\lceil \frac{2k}{3} \right\rceil\).

**Proof:** If there is an even \(r\) with \(2 \leq r \leq \left\lceil \frac{2k}{3} \right\rceil\) such that \(d_r \leq k - \left\lceil \frac{r^2}{2} \right\rceil - 1 = k - \frac{r + 1}{2} - 1\), then
\[
\sigma(\pi) \leq (r-1)(n-1) + (k - \frac{r+1}{2} - 1)(n - r + 1) = \frac{r^2}{2} - r(k - \frac{r}{2} + \frac{1}{2}) + kn - 2n + k.
\]
Denote \(f(r) = \frac{r^2}{2} - r(k - \frac{r}{2} + \frac{1}{2}) + kn - 2n + k\). Since \(2 \leq r \leq \frac{2k+2}{3}\), we have that
\[
\sigma(\pi) \leq f(r) \leq \max \{f(2), f(\frac{2k+2}{3})\} = \max \{\frac{4kn}{3} - \frac{5n}{3} - \left(\frac{k-2n}{3}\right)k - 1\}, \frac{4kn}{3} - \frac{5n}{3} - \frac{4(k^2-k+1)}{9}\}
\]
a contradiction.

If there is an odd \(r\) with \(1 \leq r \leq \left\lceil \frac{2k}{3} \right\rceil\) such that \(d_r \leq k - \left\lceil \frac{r^2}{2} \right\rceil - 1 = k - \frac{r+1}{2} - 1\), then
\[
\sigma(\pi) \leq (r-1)(n-1) + (k - \frac{r+1}{2} - 1)(n - r + 1) = \frac{r^2}{2} - r(k - \frac{r}{2} + \frac{1}{2}) + kn - 2n + k - \frac{5n}{2} - \frac{1}{2}.
\]
Denote \(g(r) = \frac{r^2}{2} - r(k - \frac{r}{2} + \frac{1}{2}) + kn - \frac{5n}{2} - \frac{1}{2}\). Since \(1 \leq r \leq \frac{2k+2}{3}\), we have that
\[
\sigma(\pi) \leq g(r) \leq \max \{g(1), g(\frac{2k+2}{3})\} = \max \{\frac{4kn}{3} - \frac{5n}{3} - \frac{kn}{3} - \frac{n}{3}, \frac{4kn}{3} - \frac{13n}{6} - \frac{4k^2}{9} + \frac{7k}{9} - \frac{5n}{3}\}
\]
a contradiction.

\[\square\]

**Lemma 2.4** Let \(k \geq 6, n \geq k\) and \(\pi = (d_1, \ldots, d_n) \in GS_n\) with \(\sigma(\pi) > \frac{4kn}{3} - \frac{5n}{3}\). Then \(d_i \geq 2(k + 1 - i)\) for \(i = \left\lceil \frac{2k}{3} \right\rceil + 1, \ldots, k\).

**Proof:** If there is an \(r\) with \(\left\lceil \frac{2k}{3} \right\rceil + 1 \leq r \leq k\) such that \(d_r \leq 2k - 2r + 1\), then by Theorem 2.2
\[
\sigma(\pi) = \sum_{i=1}^{n} d_i = \sum_{i=1}^{r-1} d_i + \sum_{i=r}^{n} d_i \leq ((r-2)(r-1) + \sum_{i=r}^{n} \min\{r-1, d_i\}) + \sum_{i=r}^{n} d_i = (r-2)(r-1) + 2 \sum_{i=r}^{n} d_i \leq (r-2)(r-1) + 2(2k-2r+1)(n-r+1) = 5r^2 - (4k + 4n + 9)r + 4kn + 4k + 2n + 4.
\]
Denote \( f(r) = 5r^2 - (4k + 4n + 9)r + 4kn + 4k + 2n + 4 \). Since \( \frac{2k+3}{3} \leq r \leq k \), we have that

\[
\sigma(\pi) \leq f(r) \leq \max\{f(\frac{2k+3}{3}), f(k)\} = \max\{\frac{4k^3}{3} - \frac{2mn}{3} - \frac{4k^2}{m} + \frac{2k}{m}, k^2 - 5k + 2n + 4\} < \max\{\frac{4kn}{5} - \frac{5n}{3} - \left(\frac{2k}{3}\right)^2 - \frac{2k}{3} - \frac{mn}{3}, \frac{4kn}{5} - \frac{5n}{3} - \left\lfloor(k - 3)\left(\frac{4n}{3} - k\right) + \frac{n}{3} + 2k - 4\right\rfloor\}
\]

a contradiction. \( \square \)

We now define a new graph \( G(k) \) as follows: Let \( V(K_{\frac{2k+n}{3}}) = \{v_1, v_2, \ldots, v_{\frac{2k+n}{3}}\} \), and \( G(k) \) be the graph obtained from \( K_{\frac{2k+n}{3}} \) by adding new vertices \( x_1, x_2, \ldots, x_{\left\lfloor\frac{k}{2}\right\rfloor} \) and joining \( x_i \) to \( v_1, v_2, \ldots, v_{2i} \) for \( 1 \leq i \leq \left\lfloor\frac{k}{2}\right\rfloor \). It is easy to see that \( |V(G(k))| = k \).

**Lemma 2.5** If \( G \) is a 2-tree on \( k \) vertices, then \( G(k) \) contains \( G \) as a subgraph.

**Proof:** We use induction on \( k \). It is easy to check that Lemma 2.5 holds for \( k = 3, 4, 5 \). If \( G = T(k) \), then it is easy to see that \( G(k) \) contains \( G \) as a subgraph. Assume that \( k \geq 6 \) and \( G \neq T(k) \). Let \( xy \in C(G) \) so that \( xy \) is attached to as few ears as possible, and let \( s \) be the number of these ears. Denote \( H = G \setminus (B(xy) \cup \{x, y\}) \). By Lemma 2.2 \( H \) is a spanning subgraph of some 2-tree \( G' \) on \( k - s - 2 \) vertices. Denote \( m = k - s - 2 \). We consider the following cases.

**Case 1.** \( k \equiv 0 \) (mod 3) and \( m \equiv 0 \) (mod 3).

Let

\[
M = G(k) - \{v_1, \ldots, v_{2k-2m}\} - \{x_1, \ldots, x_{k-m}\}.
\]

Then \( M = G(m) \). By the induction hypothesis, \( G(m) \) contains \( G' \) as a subgraph. This implies that \( G(m) \) contains \( H \) as a subgraph. Putting \( x \) and \( y \) on \( v_1 \) and \( v_2 \) respectively and taking \( B(xy) = \{v_3, \ldots, v_{2k-2m}, x_1, \ldots, x_{k-m}\} \), we can see that \( G(k) \) contains \( G \) as a subgraph.

**Case 2.** \( k \equiv 0 \) (mod 3) and \( m \equiv 1 \) (mod 3).

Let

\[
M = G(k) - \{v_1, \ldots, v_{2k-2m-4}, v_{2k}\} - \{x_1, \ldots, x_{k-m-2}, x_{k}\}.
\]

Then \( M = G(m) \). By the induction hypothesis, \( G(m) \) contains \( G' \) as a subgraph, and hence contains \( H \) as a subgraph. Putting \( x \) and \( y \) on \( v_1 \) and \( v_2 \) respectively and taking

\[
B(xy) = \{v_3, \ldots, v_{2k-2m-4}, v_{2k}, x_1, \ldots, x_{k-m-2}, x_{k}\},
\]

we can see that \( G(k) \) contains \( G \) as a subgraph.

**Case 3.** \( k \equiv 0 \) (mod 3) and \( m \equiv 2 \) (mod 3).

Let

\[
M = G(k) - \{v_1, \ldots, v_{2k-2m-2}\} - \{x_1, \ldots, x_{k-m-1}, x_k\}.
\]

Then \( M = G(m) \). By the induction hypothesis, \( G(m) \) contains \( H \) as a subgraph. Clearly, \( G(k) \) contains \( G \) as a subgraph.

**Case 4.** \( k \equiv 1 \) (mod 3) and \( m \equiv 0 \) (mod 3).

Let

\[
M = G(k) - \{v_1, \ldots, v_{2k-2m-2}, v_{2k+1}\} - \{x_1, \ldots, x_{k-m-1}\}.
\]
Then \( M = G(m) \). By the induction hypothesis, \( G(m) \) contains \( H \) as a subgraph. Clearly, \( G(k) \) contains \( G \) as a subgraph.

**Case 5.** \( k \equiv 1(\text{mod } 3) \) and \( m \equiv 1(\text{mod } 3) \).

Let
\[
M = G(k) - \{v_1, \ldots, v_{2k-2m}\} - \{x_1, \ldots, x_{k-m}\}.
\]

Then \( M = G(m) \). By the induction hypothesis, \( G(m) \) contains \( H \) as a subgraph. Clearly, \( G(k) \) contains \( G \) as a subgraph.

**Case 6.** \( k \equiv 1(\text{mod } 3) \) and \( m \equiv 2(\text{mod } 3) \).

Let
\[
M = G(k) - \{v_1, \ldots, v_{2k-2m-4}, v_{2k+1}\} - \{x_1, \ldots, x_{k-m-2}, x_{k-1}\}.
\]

Then \( M = G(m) \). By the induction hypothesis, \( G(m) \) contains \( H \) as a subgraph. Clearly, \( G(k) \) contains \( G \) as a subgraph.

**Case 7.** \( k \equiv 2(\text{mod } 3) \) and \( m \equiv 0(\text{mod } 3) \).

Let
\[
M = G(k) - \{v_1, \ldots, v_{2k-2m}, v_{2k+1}\} - \{x_1, \ldots, x_{k-m}\}.
\]

Then \( M = G(m) \). By the induction hypothesis, \( G(m) \) contains \( H \) as a subgraph. Clearly, \( G(k) \) contains \( G \) as a subgraph.

**Case 8.** \( k \equiv 2(\text{mod } 3) \) and \( m \equiv 1(\text{mod } 3) \).

Let
\[
M = G(k) - \{v_1, \ldots, v_{2k-2m-4}, v_{2k+1}\} - \{x_1, \ldots, x_{k-m-1}\}.
\]

Then \( M = G(m) \). By the induction hypothesis, \( G(m) \) contains \( H \) as a subgraph. Clearly, \( G(k) \) contains \( G \) as a subgraph.

**Case 9.** \( k \equiv 2(\text{mod } 3) \) and \( m \equiv 2(\text{mod } 3) \).

Let
\[
M = G(k) - \{v_1, \ldots, v_{2k-2m}\} - \{x_1, \ldots, x_{k-m}\}.
\]

Then \( M = G(m) \). By the induction hypothesis, \( G(m) \) contains \( H \) as a subgraph. Clearly, \( G(k) \) contains \( G \) as a subgraph.

We now define sequence \( \pi_0, \pi_1, \ldots, \pi_k \) as follows. Let \( \pi_0 = \pi \). We define the sequence
\[
\pi_1 = (d_2^{(1)}, \ldots, d_k^{(1)}, d_{k+1}^{(1)}, \ldots, d_n^{(1)})
\]
from \( \pi_0 \) by deleting \( d_1 \), decreasing the first \( d_1 \) remaining nonzero terms each by one unity, and then reordering the last \( n - k \) terms to be non-increasing. Note that the definition of the residual sequence obtained from \( \pi \) by laying off \( d_k \) is to reorder all the remaining terms to be non-increasing.

For \( 2 \leq i \leq k \), we define the sequence
\[
\pi_i = (d_1^{(i)}, \ldots, d_k^{(i)}, d_{k+1}^{(i)}, \ldots, d_n^{(i)})
\]
from
\[
\pi_{i-1} = (d_1^{(i-1)}, \ldots, d_k^{(i-1)}, d_{k+1}^{(i-1)}, \ldots, d_n^{(i-1)})
\]
by deleting \( d_i^{(i-1)} \), decreasing the first \( d_i^{(i-1)} \) remaining nonzero terms each by one unity, and then reordering the last \( n - k \) terms to be non-increasing.
Lemma 2.6  Let $k \geq 6$, $n \geq k$ and $\pi = (d_1, \ldots, d_{\lceil \frac{n}{3k} \rceil}, d_{\lfloor \frac{n}{3k} \rfloor+1}, \ldots, d_k, d_{k+1}, \ldots, d_n) \in GS_n$ satisfy $d_i \geq k - \lceil \frac{i}{2} \rceil$ for $i = 1, \ldots, \lceil \frac{2n}{3k} \rceil$. If $\pi_k$ is graphic, then $\pi$ has a realization containing $G(k)$ as a subgraph.

Proof: Suppose that $\pi_k$ is realized by graph $G_k$ with vertex set $V(G_k) = \{v_{k+1}, \ldots, v_n\}$ such that $d_{G_k}(v_i) = d_i^{(k)}$ for $1 \leq i \leq n$. For $i = k-1, 1$ in turn, form $G_{i-1}$ from $G_i$ by adding a new vertex $v_i$ that is adjacent to the vertices of $G_i$ whose degrees are reduced by one in going from $\pi_{i-1}$ to $\pi_i$. Then, for each $i$, $G_i$ has degrees given by $\pi_i$. In particular, $G_0$ has degrees given by $\pi$. Since $\pi$ satisfies $d_i \geq k - \lceil \frac{i}{2} \rceil$ for $i = 1, \ldots, \lceil \frac{2n}{3k} \rceil$, by the definition of $\pi_i$ for $i = 1, \ldots, k$ in turn, we can see that $G_0[\{v_1, \ldots, v_k\}]$ contains $G(k)$ as a subgraph. \hfill $\square$

Lemma 2.7  Let $k \geq 6$, $n \geq k$ and $\pi = (d_1, \ldots, d_{\lceil \frac{n}{3k} \rceil}, d_{\lfloor \frac{n}{3k} \rfloor+1}, \ldots, d_k, d_{k+1}, \ldots, d_n) \in GS_n$. Let $\pi_1 = (d_1', \ldots, d_{n-1}')$ be the residual sequence obtained from $\pi$ by laying off $d_1$ and $\rho = (\rho_1, \ldots, \rho_{n-2})$ be the residual sequence obtained from $\pi_1$ by laying off the term $d_2 - 1$. If $\pi$ satisfies one of (a)-(c), where

(a) $d_1 = d_2 = n - 1$,
(b) $d_1 = n - 1$, $d_2 \leq n - 2$ and $d_k > d_{d_2+2}$,
(c) $d_1 \leq n - 2$, $d_k > d_{d_2+2}$ and $d_k - d_{d_2+2} \geq 2$,

then $\rho_1 = d_3 - 2, \rho_2 = d_4 - 2, \ldots, \rho_{k-2} = d_k - 2$.

Proof: If $\pi$ satisfies (a), then $\rho = (d_3 - 2, \ldots, d_n - 2)$, and so $\rho_1 = d_3 - 2, \rho_2 = d_4 - 2, \ldots, \rho_{k-2} = d_k - 2$.

If $\pi$ satisfies (b), then $\rho_1 = (d_2 - 1, \ldots, d_n - 1)$. By $d_k - 2 \geq d_{d_2+2} - 1$, we further have that

$\rho_1 = d_3 - 2, \rho_2 = d_4 - 2, \ldots, \rho_{k-2} = d_k - 2$.

Assume that $\pi$ satisfies (c). If $d_{d_2+2} > d_{d_2+2}$, then $d_{d_2+2} - 1 \geq d_{d_2+2}$, and hence $d_1' = d_2 - 1, \ldots, d_{d_2+1}' = d_{d_2+2} - 1$. By $d_k > d_{d_2+2}$, we have $d_k - 2 \geq d_{d_2+2} - 1$, implying that $\rho_1 = d_3 - 2, \rho_2 = d_4 - 2, \ldots, \rho_{k-2} = d_k - 2$. If $d_{d_2+2} = \cdots = d_{d_2+2}$, then $d_{d_2+2} - 1 < d_{d_2+2}$. By $d_k - d_{d_2+2} \geq 2$, we have $d_1' = d_2 - 1, \ldots, d_{d_2+1}' = d_{d_2+2}$, and $d_{d_2+2} = d_{d_2+2}$, implying that $\rho_1 = d_3 - 2, \rho_2 = d_4 - 2, \ldots, \rho_{k-2} = d_k - 2$. \hfill $\square$

Lemma 2.8  Let $k \geq 6$, $n \geq k$ and $\pi = (d_1, \ldots, d_{\lceil \frac{n}{3k} \rceil}, d_{\lfloor \frac{n}{3k} \rfloor+1}, \ldots, d_k, d_{k+1}, \ldots, d_n) \in GS_n$. For each $\pi_i = (d_1^{(i)}, \ldots, d_k^{(i)}, d_{k+1}^{(i)}, \ldots, d_n^{(i)})$, let $t_i = \max\{j|d_{k+1}^{(i)} - d_{k+j}^{(i)} \leq 1\}$.

(1) If $\pi$ satisfies (d) or (e), where

(d) $d_1 \leq n - 2$, $d_k > d_{d_2+2}$ and $d_k - d_{d_2+2} \leq 1$,
(e) $d_1 \leq n - 2$, $d_k = d_{d_2+2}$ and $d_{d_2+2} = d_{d_2+1}$,

then $d_{k+r}^{(i)} = d_{k+r}^{(i)}$ for $r > t_k$.

(2) If $\pi$ satisfies (f) or (g), where

(f) $d_1 = n - 1$, $d_2 \leq n - 2$ and $d_k = d_{d_2+2}$,
(g) $d_1 \leq n - 2$, $d_k = d_{d_2+2}$ and $d_{d_2+2} > d_{d_2+1}$,

then $d_{k+r}^{(i)} = d_{k+r}^{(i)}$ for $r > t_k$.

Proof: (1) If $\pi$ satisfies (d) or (e), then $k + t_0 \geq d_1 + 2$. Since $d_{k+1}^{(i-1)} - d_{k+t_1}^{(i-1)} \leq 1$ implies that

$d_{k+1}^{(i)} - d_{k+t_1}^{(i)} \leq 1$ for $1 \leq i \leq k$, we have that $t_k \geq t_{k-1} \geq \cdots \geq t_0 \geq d_1 + 2 - k$. By

min$\{d_{k+1}^{(i-1)} - 1, \ldots, d_{d_1+1}^{(i-1)} - 1, d_{d_2+2}^{(i-1)}, \ldots, d_{k+t_1-1}^{(i-1)}\} \geq d_{k+1}^{(i-1)} - 2 \geq d_{k+t_1-1}^{(i-1)} \geq \cdots \geq d_n^{(i-1)}$,
Let is easy to see that if \( k \pi d \) that \( d \), we have that \( d_{k+t_i-1} = d_{k+t_i-1}^{'(i)} \) for \( r > t_i \). This implies that \( d_{k+r} = d_{k+r} \) for \( r > t_k \).

(2) If \( \pi \) satisfies (f) or (g), then \( t_k \geq t_k-1 \geq \cdots \geq t_1 \geq t_0 \geq d_2 + 2 - k \). Since \( \min\{d_{k+1}^{(i)} - 1, \ldots, d_{k+1}^{(i)} - 1, d_{k+2}^{(i)} \} \geq d_{k+1}^{(i)} - 2 \geq d_{k+t_i-1} \geq \cdots \geq d_{n}^{(i)} \) for \( i \geq 2 \), we have that \( d_{k+t_i-1+m} = d_{k+t_i-1}^{'(i)} + m \) for \( i \geq 2 \) and \( m \geq 1 \). Thus, \( d_{k+r} = d_{k+r} \) for \( i \geq 2 \) and \( r > t_i \). This implies that \( d_{k+r} = d_{k+r} \) for \( r > t_k \).

\[ \pi = (d_1, \ldots, d_n) \in GS_n \] if \( \pi \) has a realization containing every 2-tree on \( k \) vertices as a subgraph, then \( \pi \) is potentially \( A'(k) \)-graphic. If \( \pi \) has a realization in which the subgraph induced by the \( k \) vertices of largest degrees contains every 2-tree on \( k \) vertices as a subgraph, then \( \pi \) is potentially \( A''(k) \)-graphic. It is easy to see that if \( \pi \) is potentially \( A''(k) \)-graphic, then \( \pi \) is potentially \( A'(k) \)-graphic.

**Lemma 2.9** Let \( k \geq 3 \), \( n \geq 6k \) and \( \pi = (d_1, \ldots, d_n) \in GS_n \) with \( d_n \geq 2 \frac{k}{3} - 2 \) and \( \sigma(\pi) > 4 \frac{kn}{3} - 5 \frac{n}{3} \). Then \( \pi \) is potentially \( A''(k) \)-graphic.

**Proof:** We use induction on \( k \). If \( k = 3 \), then by \( \sigma(\pi) > 4 \frac{kn}{3} - 5 \frac{n}{3} \geq 2n \) and Theorem 2.7 (1), \( \pi \) has a realization containing \( K_3 \). By Theorem 2.4, \( \pi \) is potentially \( A'(3) \)-graphic. If \( k = 4 \), then by \( \sigma(\pi) > 4 \frac{kn}{3} - 5 \frac{n}{3} \geq 3n - 1 \) and Theorem 2.7 (2), \( \pi \) has a realization containing \( K_4 - e \). By Theorem 2.4, \( \pi \) is potentially \( A''(4) \)-graphic. If \( k = 5 \), then by \( \sigma(\pi) > 4 \frac{kn}{3} - 5 \frac{n}{3} \geq 5n - 6 \) and Theorem 2.7 (3), \( \pi \) has a realization containing \( K_5 - e \). Since \( K_5 - e \) contains every 2-tree on 5 vertices, by Theorem 2.4, \( \pi \) is potentially \( A''(5) \)-graphic. Assume \( k \geq 6 \). We only need to prove that \( \pi = (d_1, \ldots, d_n) \) has a realization in which the subgraph induced by the vertices with degrees \( d_1, \ldots, d_k \) contains every 2-tree on \( k \) vertices. Let \( \pi_1' = (d_1', \ldots, d_{n-1}') \) be the residual sequence obtained from \( \pi \) by laying off \( d_1 \) and \( \rho = (\rho_1, \ldots, \rho_{n-2}) \) be the residual sequence obtained from \( \pi_1' \) by laying off the term \( d_2 - 1 \). Then \( n - 2 \geq 6(k - 3) \), \( \rho_{n-2} \geq \left( \frac{2k}{3} - 2 \right) - 2 = \frac{2(k-3)}{3} - 2 \) and \( \sigma(\rho) = \sigma(\pi) - 2d_1 - 2d_2 + 2 > \frac{4kn}{3} - 5 \frac{n}{3} - 4(n - 1) + 2 > \frac{4(k-3)(n-2)}{3} - 5 \frac{n-2}{3} \). By the induction hypothesis, \( \rho \) has a realization \( G_1 \) in which the subgraph induced by the vertices with degrees \( \rho_1, \ldots, \rho_{k-3} \) contains every 2-tree on \( k - 3 \) vertices. Denote \( F \) to be the subgraph induced by the vertices with degrees \( \rho_1, \ldots, \rho_{k-3} \) in \( G_1 \), and let \( F' \) be the graph obtained from \( F \) by adding three new vertices \( x, y, u \) such that \( x, y \) are adjacent to each vertex of \( F \) and \( xy, xu, yu \in E(F') \).

**Claim** \( F' \) contains every 2-tree on \( k \) vertices.

**Proof of Claim.** Let \( G \) be any one 2-tree on \( k \) vertices. Take \( xy \in C(G) \) and \( u \in B(xy) \), and denote \( H = G \setminus \{x, y, u\} \). By Lemma 2.3, it is easy to get that \( H \) is a spanning subgraph of some 2-tree on \( k - 3 \) vertices. Since \( F \) contains every 2-tree on \( k - 3 \) vertices, we have that \( F \) contains \( H \) as a subgraph. By the definition of \( F' \), we can see that \( F' \) contains \( G \) as a subgraph. By the arbitrary of \( G \), \( F' \) contains every 2-tree on \( k \) vertices. This proves Claim.

If \( \pi \) satisfies one of (a)-(c), by Lemma 2.7, then \( \rho_1 = d_3 - 2, \rho_2 = d_4 - 2, \ldots, \rho_{k-2} = d_k - 2 \). Now by the definitions of \( \rho \) and \( \pi_1' \), it is easy to get that \( \pi \) has a realization \( G' \) in which the subgraph induced by the vertices with degrees \( d_1, \ldots, d_k \) contains \( F' \) as a subgraph. Thus by Claim, \( \pi \) has a realization in which the subgraph induced by the vertices with degrees \( d_1, \ldots, d_k \) contains every 2-tree on \( k \) vertices.
An extremal problem of graphic sequences with a realization containing every 2-tree with given size

We now assume that $\pi$ satisfies one of (d)--(g). If $d_k \geq 2k - 3$, then by Theorem 2.5 $\pi$ has a realization containing $K_k$, and hence $\pi$ is potentially $\alpha''(k)$-graphic by Theorem 2.4. Assume that $d_k \leq 2k - 4$. By $\sigma(\pi) > \frac{4kn}{3} - \frac{5n}{3}$ and Lemmas 2.3 and 2.4, we have that $d_i \geq k - \left\lceil \frac{i}{2} \right\rceil$ for $i = 1, \ldots, \left\lceil \frac{2k}{3} \right\rfloor$ and $d_{\left\lceil \frac{2k}{3} \right\rceil + 1} \geq 2\left\lceil \frac{k}{3} \right\rceil$. It is enough to prove that $\pi_k$ is graphic by Theorem 2.4 and Lemmas 2.5 and 2.6. If $\pi$ satisfies (d) or (e), by Lemma 2.8(1), then

$$
\pi_k = (d^{(k)}_{k+1}, \ldots, d^{(k)}_{k+t_k}, d_{k+t_k+1}, \ldots, d_n).
$$

If $\pi$ satisfies (f) or (g), by Lemma 2.8(2), then

$$
\pi_k = (d^{(k)}_{k+1}, \ldots, d^{(k)}_{k+t_k}, d^{(1)}_{k+t_k+1}, \ldots, d^{(1)}_n).
$$

If $t_k < n - k$, then $k + t_k < n$. By $d^{(k)}_{k+1} \leq d_{k+1} \leq d_k \leq 2k - 4$, then $d_n \geq d^{(1)}_n \geq d_n - 1 \geq \frac{2k}{3} - 3 \geq 1$, we have that $d^{(k)}_{k+1} \leq 2k - 4$ and $d_n \geq d^{(1)}_n \geq \left\lceil \frac{2k}{3} - 3 \right\rceil \geq 1$. Since $\frac{(2k-3+x)^2}{4x}$ is a monotone decreasing function of $x$ on the interval $(0, 2k-3]$, by $\left\lceil \frac{2k}{3} - 3 \right\rceil \geq \frac{2k}{3} - 3$, we have that

$$
\frac{1}{\left\lceil \frac{2k}{3} - 3 \right\rceil} \frac{(2k-4+1)^2}{4} \leq \frac{(2k-3+1)^2}{4(\frac{2k}{3} - 3)^2} \leq \frac{1}{\left\lceil \frac{2k}{3} - 3 \right\rceil} \leq \frac{2k-9}{3} + 3 \leq n - k.
$$

By Theorem 2.3, $\pi_k$ is graphic. If $t_k = n - k$, then $d^{(k)}_{k+1} - d^{(k)}_n \leq 1$. Denote $d^{(k)}_n = m$. If $m = 0$, then by $d^{(k)}_{k+1} \leq 1$ and $\sigma(\pi_k)$ being even, $\pi_k$ is clearly graphic. If $m \geq 1$, then $d^{(k)}_{k+1} \leq m + 1$, and hence

$$
\frac{1}{m} \left( \frac{m + 1 + m + 1}{4} \right) = \frac{(m + 1)^2}{m} \leq m + 3 \leq 2k - 4 + 3 \leq n - k.
$$

By Theorem 2.3, $\pi_k$ is also graphic. 

**Lemma 2.10** Let $k \geq 6$, $n = 6k$ and $\pi = (d_1, \ldots, d_n) \in GS_n$ with $\sigma(\pi) > \frac{4kn}{3} - \frac{5n}{3} + 4k^2 - 14k$. Then $\pi$ is potentially $\alpha''(k)$-graphic.

**Proof:** By $\sigma(\pi) \geq \frac{4kn}{3} - \frac{5n}{3} + 4k^2 - 14k + 2 = 2n(k-2) + 2$ and Theorem 2.6, $\pi$ has a realization containing $K_k$. By Theorem 2.4, $\pi$ is potentially $\alpha''(k)$-graphic. 

**Lemma 2.11** Let $k \geq 6$ and $n = 6k + t$, where $0 \leq t \leq 2k^2 - 7k$. If $\pi = (d_1, \ldots, d_n) \in GS_n$ with $\sigma(\pi) > \frac{4kn}{3} - \frac{5n}{3} + 4k^2 - 14k - 2t$, then $\pi$ is potentially $\alpha'(k)$-graphic.

**Proof:** We use induction on $t$. It is known from Lemma 2.10 that Lemma 2.11 holds for $t = 0$. Suppose now that $1 \leq t \leq 2k^2 - 7k$. Then $\sigma(\pi) > \frac{4kn}{3} - \frac{5n}{3}$. If $d_n \geq \frac{2k}{3} - 2$, then $\pi$ is potentially $\alpha''(k)$-graphic by Lemma 2.9. If $d_n < \frac{2k}{3} - 2$, then the residual sequence $\pi'_n = (d'_1, \ldots, d'_{n-1})$ obtained by
laying off $d_n$ from $\pi$ satisfies $\sigma(\pi'_n) = \sigma(\pi) - 2d_n > \frac{4kn}{3} - \frac{5n}{3} + 4k^2 - 14k - 2t - 2(\frac{2k}{n} - 2) > \frac{4k(n-1)}{3} - \frac{5(n-1)}{3} + 4k^2 - 14k - 2(t - 1)$. By the induction hypothesis, $\pi'_n$ is potentially $A'(k)$-graphic, and hence so is $\pi$.

We now prove Theorem 1.2.

**Proof of Theorem 1.2** Let $k \geq 3$, $n \geq 2k^2 - k$ and $\pi = (d_1, \ldots, d_n) \in GS_n$ with $\sigma(\pi) > \frac{4kn}{3} - \frac{5n}{3}$. We only need to prove that $\pi$ is potentially $A'(k)$-graphic. If $k = 3$, then by $\sigma(\pi) > \frac{4kn}{3} - \frac{5n}{3} \geq 2n$ and Theorem 2.7 (1), $\pi$ has a realization containing $K_3$, and hence $\pi$ is potentially $A'(3)$-graphic. If $k = 4$, then by $\sigma(\pi) > \frac{4kn}{3} - \frac{5n}{3} \geq 3n - 1$ and Theorem 2.7 (2), $\pi$ has a realization containing $K_4 - e$, and hence $\pi$ is potentially $A'(4)$-graphic. If $k = 5$, then by $\sigma(\pi) > \frac{4kn}{3} - \frac{5n}{3} \geq 5n - 6$ and Theorem 2.7 (3), $\pi$ has a realization containing $K_5 - e$. Since $K_5 - e$ contains every 2-tree on 5 vertices, $\pi$ is potentially $A'(5)$-graphic. Assume that $k \geq 6$. We now use induction on $n$. If $n = 2k^2 - k$, then by Lemma 2.11 ($t = 2k^2 - 7k$), $\pi$ is potentially $A'(k)$-graphic. Assume that $n \geq 2k^2 - k + 1$. If $d_n \geq \frac{2k}{3} - 2$, then by Lemma 2.9 $\pi''$ is potentially $A'(k)$-graphic. If $d_n < \frac{2k}{3} - 2$, then the residual sequence $\pi''_n = (d'_1, \ldots, d'_{n-1})$ obtained from $\pi$ by laying off $d_n$ satisfies $\sigma(\pi''_n) = \sigma(\pi) - 2d_n > \frac{4kn}{3} - \frac{5n}{3} - 2(\frac{2k}{n} - 2) > \frac{4k(n-1)}{3} - \frac{5(n-1)}{3}$. By the induction hypothesis, $\pi''_n$ is potentially $A'(k)$-graphic, and hence so is $\pi$.

3 Proof of Theorem 1.3

In order to prove Theorem 1.3, we recursively define a new graph $F(k)$ on $k \geq 3$ vertices as follows. Let $F(3) = K_3$, and let $V(F(k - 1)) = \{x_1, \ldots, x_{k-1}\}$ for $k \geq 4$. Define $F(k)$ be the graph obtained from $F(k - 1)$ by adding a new vertex $x_k$ and joining $x_k$ to $x_{k-2}$ and $x_{k-1}$. Clearly, $F(k)$ is a 2-tree on $k$ vertices. Let $\alpha(G)$ denote the independence number of $G$. We need the following Lemma 3.1

**Lemma 3.1** Let $k \geq 3$ and $e \in E(F(k))$. Then

1. $\alpha(F(k)) \leq \left\lceil \frac{k}{3} \right\rceil$;
2. If $k \equiv 1 \pmod{3}$, then $\alpha(F(k) - e) \leq \left\lceil \frac{k}{3} \right\rceil$.

**Proof:** (1) We use induction on $k$. It is easy to check that Lemma 3.1 (1) holds for $k = 3, 4, 5$. Assume that $k \geq 6$. Let $V(F(k)) = \{x_1, \ldots, x_k\}$. By the construction of $F(k)$, we have that the subgraph induced by $\{x_{k-2}, x_{k-1}, x_k\}$ in $F(k)$ is $K_3$. Let $X$ be a maximum independent set of $F(k)$. Then $|\{x_{k-2}, x_{k-1}, x_k\} \cap X| \leq 1$. If $|\{x_{k-2}, x_{k-1}, x_k\} \cap X| = 0$, then $X$ is an independent set of $F(k) - \{x_{k-2}, x_{k-1}, x_k\} = F(k - 3)$. By the induction hypothesis, we have that $\alpha(F(k)) = |X| \leq \alpha(F(k - 3)) \leq \left\lceil \frac{k-3}{3} \right\rceil \leq \left\lceil \frac{k}{3} \right\rceil$. If $|\{x_{k-2}, x_{k-1}, x_k\} \cap X| = 1$, let $\{x_{k-2}, x_{k-1}, x_k\} \cap X = \{x\}$, then $X \setminus \{x\}$ is an independent set of $F(k) - \{x_{k-2}, x_{k-1}, x_k\} = F(k - 3)$. By the induction hypothesis, we have that $\alpha(F(k)) - 1 = |X \setminus \{x\}| \leq \alpha(F(k - 3)) \leq \left\lceil \frac{k-3}{3} \right\rceil$, i.e., $\alpha(F(k)) \leq \left\lceil \frac{k-3}{3} \right\rceil + 1 = \left\lceil \frac{k}{3} \right\rceil$.

(2) Clearly, Lemma 3.1 (2) holds for $k = 4$. By the construction of $F(k)$, we have that $e = x_ix_{i+1}$ for $1 \leq i \leq k - 1$ or $e = x_jx_{j+2}$ for $1 \leq j \leq k - 2$. Let $X$ be a maximum independent set of $F(k) - e$.

Firstly, we assume that $e = x_ix_{i+1}$ for $1 \leq i \leq k - 1$. If $|\{x_i, x_{i+1}\} \cap X| \leq 1$, then $X$ is an independent set of $F(k)$, and hence $\alpha(F(k) - e) = |X| \leq \alpha(F(k)) \leq \left\lceil \frac{k}{3} \right\rceil$. Assume that $|\{x_i, x_{i+1}\} \cap X| = 2$, i.e., $\{x_i, x_{i+1}\} \subseteq X$. If $i = 1$ (or $i = k - 1$), then $X \setminus \{x_1, x_2\}$ (or $X \setminus \{x_{k-1}, x_k\}$) is an independent set of
An extremal problem of graphic sequences with a realization containing every 2-tree with given size 325

\[ F(k) - \{x_1, x_2, x_3, x_4\} = F(k - 4) \] (or \( F(k) - \{x_k, x_{k-1}, x_{k-2}, x_{k-3}\} = F(k - 4) \)). This implies that \( \alpha(F(k) - e) - 2 = |X| - 2 \leq \alpha(F(k) - \{\alpha(F(k) - e) \}) \leq \left\lceil \frac{k-4}{3}\right\rceil \), i.e., \( \alpha(F(k) - e) \leq \left\lceil \frac{k-4}{3}\right\rceil + 2 = \left\lceil \frac{k+1}{3}\right\rceil = \left\lceil \frac{5}{3}\right\rceil \) (as \( k \equiv 1(\text{mod } 3) \)). If \( i = 2 \) (or \( i = k - 2 \)), then \( X \setminus \{x_2, x_3\} \) (or \( X \setminus \{x_{k-2}, x_{k-3}\} \)) is an independent set of \( F(k) - \{x_1, x_2, x_3, x_4, x_5\} = F(k - 5) \) (or \( F(k) - \{x_k, x_{k-1}, x_{k-2}, x_{k-3}, x_{k-4}\} = F(k - 5) \)). This implies that \( \alpha(F(k) - e) - 2 = |X| - 2 \leq \alpha(F(k) - \{\alpha(F(k) - e) \}) \leq \left\lceil \frac{k-4}{3}\right\rceil \), i.e., \( \alpha(F(k) - e) \leq \left\lceil \frac{k-4}{3}\right\rceil + 2 = \left\lceil \frac{k+1}{3}\right\rceil = \left\lceil \frac{5}{3}\right\rceil \) (as \( k \equiv 1(\text{mod } 3) \)). If \( 3 \leq i \leq k - 3 \), then \( X \setminus \{x_i, x_{i+1}\} \) is an independent set of \( F(k) - \{x_{i-2}, x_{i-1}, x_i, x_{i+1}, x_{i+2}, x_{i+3}\} \). For convenience, we denote \( F(i) = K_i \) for \( i = 1, 2 \). Clearly, \( \alpha(F(i)) \leq \left\lceil \frac{i}{3}\right\rceil \) for \( i = 1, 2 \). Since \( F(k) - \{x_1, x_2, x_3, x_4, x_5\} \) is the disjoint union of \( F(i - 3) \) and \( F(k - i - 3) \), we have that \( \alpha(F(k) - e) - 2 = |X| - 2 \leq \alpha(F(k) - \{\alpha(F(k) - e) \}) \leq \left\lceil \frac{k-4}{3}\right\rceil \), i.e., \( \alpha(F(k) - e) \leq \left\lceil \frac{k-4}{3}\right\rceil + 2 = \left\lceil \frac{k+1}{3}\right\rceil = \left\lceil \frac{5}{3}\right\rceil \) (as \( k \equiv 1(\text{mod } 3) \)). If \( j = 2 \) (or \( j = k - 3 \)), then \( X \setminus \{x_2, x_4\} \) (or \( X \setminus \{x_{k-3}, x_{k-1}\} \)) is an independent set of \( F(k) - \{x_1, x_2, x_3, x_4, x_5\} = F(k - 6) \) (or \( F(k) - \{x_k, x_{k-1}, x_{k-2}, x_{k-3}, x_{k-4}, x_{k-5}\} = F(k - 6) \)). This implies that \( \alpha(F(k) - e) - 2 = |X| - 2 \leq \alpha(F(k) - \{\alpha(F(k) - e) \}) \leq \left\lceil \frac{k-6}{3}\right\rceil \), i.e., \( \alpha(F(k) - e) \leq \left\lceil \frac{k-6}{3}\right\rceil + 2 = \left\lceil \frac{k+1}{3}\right\rceil = \left\lceil \frac{5}{3}\right\rceil \) (as \( k \equiv 1(\text{mod } 3) \)). If \( 3 \leq j \leq k - 4 \), then \( X \setminus \{x_j, x_{j+2}\} \) is an independent set of \( F(k) - \{x_{j-2}, x_{j-1}, x_j, x_{j+1}, x_{j+2}, x_{j+3}, x_{j+4}\} \). For \( F(k) - \{x_j, x_{j-1}, x_j, x_{j+1}, x_{j+2}, x_{j+3}, x_{j+4}\} \) is the disjoint union of \( F(j - 3) \) and \( F(k - j - 4) \), we have that \( \alpha(F(k) - e) - 2 = |X| - 2 \leq \alpha(F(k) - \{\alpha(F(k) - e) \}) \leq \left\lceil \frac{k-6}{3}\right\rceil \), i.e., \( \alpha(F(k) - e) \leq \left\lceil \frac{k-6}{3}\right\rceil + 2 = \left\lceil \frac{k+1}{3}\rceil = \left\lceil \frac{5}{3}\right\rceil \) (as \( k \equiv 1(\text{mod } 3) \)).

**Proof of Theorem 3.1** Let \( k \geq 3 \) with \( k \equiv i(\text{mod } 3) \). Denote \( H = P_5 \cdot e + \overline{K}_{n-\left\lceil \frac{5}{3}\right\rceil+1} \). If \( H \) contains \( F(k) \) on the vertices \( u_1, \ldots, u_k \), then \( k - \left\lceil \frac{5}{3}\right\rceil - 1 \leq \alpha(H[\{u_1, \ldots, u_k\}]) \leq \alpha(F(k)) \leq \left\lceil \frac{5}{3}\right\rceil \) (Lemma 3.1.1). This is impossible as \( k - \left\lceil \frac{5}{3}\right\rceil - 1 = \left\lceil \frac{5}{3}\right\rceil + 1 \). Hence \( H \) contains no \( F(k) \).

For \( i = 0 \) or \( 2 \), we let \( \pi = (n-1)\left\lceil \frac{5}{3}\right\rceil - 1, (\left\lceil \frac{5}{3}\right\rceil - 1)^n - (\left\lceil \frac{5}{3}\right\rceil - 1) \). Then \( \pi \in GS_n, \sigma(\pi) = 2\left\lceil \frac{5}{3}\right\rceil n - 2n - \left\lceil \frac{5}{3}\right\rceil^2 + \left\lceil \frac{5}{3}\right\rceil \) and \( H \) is the unique realization of \( \pi \). Since \( H \) contains no \( F(k) \), we have that \( \pi \) has no realization containing \( F(k) \). This implies that \( \pi \) has no realization containing every 2-tree on \( k \) vertices.

For \( i = 1 \), we let \( \pi = (n-1)\left\lceil \frac{5}{3}\right\rceil - 1, (\left\lceil \frac{5}{3}\right\rceil - 1)^2, (\left\lceil \frac{5}{3}\right\rceil - 1)^n - (\left\lceil \frac{5}{3}\right\rceil - 1) \). Then \( \pi \in GS_n, \sigma(\pi) = 2\left\lceil \frac{5}{3}\right\rceil n - 2n - \left\lceil \frac{5}{3}\right\rceil^2 + \left\lceil \frac{5}{3}\right\rceil \) and \( H + e \) (a simple graph is obtained from \( H \) by adding an edge \( e \)) is the unique realization of \( \pi \). Assume that \( H + e \) contains \( F(k) \). Since \( H \) contains no \( F(k) \), we have that \( H \) contains \( F(k) - e \). If \( H \) contains \( F(k) - e \) on the vertices \( u_1, \ldots, u_k \), then \( k - \left\lceil \frac{5}{3}\right\rceil - 1 \leq \alpha(H[\{u_1, \ldots, u_k\}]) \leq \alpha(F(k) - e) \leq \left\lceil \frac{5}{3}\right\rceil \) (Lemma 3.1.2), a contradiction. Hence \( \pi \) has no realization containing \( F(k) \). This proves Theorem 3.1.

Since

\[
\lim_{n \to +\infty} \frac{4nk - 5n}{3} n - 2n - \left\lceil \frac{5}{3}\right\rceil^2 + \left\lceil \frac{5}{3}\right\rceil + 1 - (-1)^i = \frac{4k - 5}{3} - 2 \approx 1,
\]

we have that \( \frac{4kn}{3} - \frac{5n}{3} \) is almost the best possible lower bound in Theorem 1.2.
De-Yan Zeng, Jian-Hua Yin

For \( k \equiv i \pmod{3} \), we feel that \( 2\left\lfloor \frac{2k}{3} \right\rfloor n - 2n - \left\lfloor \frac{2k}{3} \right\rfloor^2 + \left\lceil \frac{2k}{3} \right\rceil + 1 - (-1)^i \) is the best possible lower bound for sufficiently large \( n \), thus we propose the following conjecture.

**Conjecture** If \( k \geq 3 \) with \( k \equiv i \pmod{3} \), \( n \) is sufficiently large, and \( \pi \in GS_n \) with \( \sigma(\pi) > 2\left\lfloor \frac{2k}{3} \right\rfloor n - 2n - \left\lfloor \frac{2k}{3} \right\rfloor^2 + \left\lceil \frac{2k}{3} \right\rceil + 1 - (-1)^i \), then \( \pi \) has a realization \( H \) containing every 2-tree on \( k \) vertices. Moreover, the lower bound \( 2\left\lfloor \frac{2k}{3} \right\rfloor n - 2n - \left\lfloor \frac{2k}{3} \right\rfloor^2 + \left\lceil \frac{2k}{3} \right\rceil + 1 - (-1)^i \) is the best possible.
