We consider the standard Quicksort algorithm that sorts \( n \) distinct keys with all possible \( n! \) orderings of keys being equally likely. Equivalently, we analyze the total path length \( \mathcal{L}_n \) in a randomly built binary search tree. Obtaining the limiting distribution of \( \mathcal{L}_n \) is still an outstanding open problem. In this paper, we establish an integral equation for the probability density of the number of comparisons \( \mathcal{C}_n \). Then, we investigate the large deviations of \( \mathcal{L}_n \). We shall show that the left tail of the limiting distribution is much “thinner” (i.e., double exponential) than the right tail (which is only exponential).

Our results contain some constants that must be determined numerically. We use formal asymptotic methods of applied mathematics such as the WKB method and matched asymptotics.

Keywords: Algorithms, Analysis of algorithms, Asymptotic analysis, Binary search tree, Quicksort, Sorting.

1 Introduction

Hoare’s Quicksort algorithm [11] is the most popular sorting algorithm due to its good performance in practise. The basic algorithm can be briefly described as follows [11, 14, 16]:

A partitioning key is selected at random from the unsorted list of keys, and used to partition the keys into two sublists to which the same algorithm is called recursively until the sublists have size one or zero.

To justify the algorithm’s good performance in practise, a body of theory was built. First of all, every undergraduate learns in a data structures course that the algorithm sorts “on average” \( n \) keys in \( \Theta(n \log n) \) steps. To be more precise, one assumes that all \( n! \) possible orderings of keys are equally likely. It is, however, also known that in the worst case the algorithm needs \( O(n^2) \) steps (e.g., think of an input that is given in a decreasing order when the output is printed in an increasing order). Thus, one needs a more detailed
probabilistic analysis to understand better the Quicksort behavior. In particular, one would like to know how likely (or rather unlikely) it is for such pathological behavior to occur.

A large body of literature is devoted to analyzing the Quicksort algorithm [4, 5, 6, 8, 14, 15, 16, 17, 18, 19, 21]. However, many aspects of this problem are still largely unsolved. To review what is known and what is still unsolved, we introduce some notation. Let \( L_n \) denote the number of comparisons needed to sort a random list of length \( n \). It is known that after selecting randomly a key, the two sublists are still “random” (cf. [14]). Clearly, the sorting time depends only on the keys’ ranking, so we assume that the input consists of the first \( n \) integers \( \{1, 2, \ldots, n\} \), and key \( k \) is chosen with probability \( 1/n \). Then, the following recurrence holds

\[
L_n = n - 1 + L_k + L_{n-1-k}.
\]

(1)

Now, let \( L_n(u) = E u^{L_n} = \sum_{k=0}^n \Pr[L_n = k] u^k \) be the probability generating function of \( L_n \). The above recurrence implies that

\[
L_n(u) = \frac{u^{n-1}}{n} \sum_{i=0}^{n-1} L_i(u)L_{n-1-i}(u)
\]

(2)

with \( L_0(u) = 1 \). Observe that the same recurrences are obtained when analyzing the total path length \( L_n \) of a binary search tree built over a random set of \( n \) keys (cf. [14, 16]). Finally, let us define a bivariate generating function \( L(z, u) = \sum_{n=0}^\infty L_n(u)z^n \). Then (2) leads to the following partial-differential functional equation

\[
\frac{\partial L(z, u)}{\partial z} = L^2(zu, u), \quad \frac{\partial L(0, u)}{\partial z} = 1.
\]

(3)

Observe also that \( L(z, 1) = (1-z)^{-1} \).

The moments of \( L_n \) are relatively easy to compute since they are related to derivatives of \( L_n(u) \) at \( u = 1 \). Hennequin [8] analyzed these carefully and computed the first five cumulants. He also conjectured an asymptotic formula for the cumulants as \( n \to \infty \) which he later proved in [9].

The main open problem is to find the limiting distribution of \( L_n \). Régnier [18] proved that the limiting distribution of \( (L_n - E[L_n])/n \) exists, while Rösler [19, 20] characterized this limiting distribution as a fixed point of a contraction satisfying a recurrence equation. A partial-differential functional equation seemingly similar to (3) was studied recently by Jacquet and Szpankowski [12]. They analyzed a digital search tree for which the bivariate generating function \( L(z, u) \) (in the so–called symmetric case) satisfies

\[
\frac{\partial L(z, u)}{\partial z} = L^2(\frac{1}{2}zu, u)
\]

(4)

with \( L(z, 0) = 1 \). The above equation was solved asymptotically in [12], and this led to a limiting normal distribution of the path length \( L_n \) in digital search trees. While the above equation and (3) look similar, there are crucial differences. Among them, the most important is the contracting factor \( \frac{1}{2} \) in the right-hand side of the above. Needless to say, we know that (3) does not lead to a normal distribution since the third central moment is not asymptotically equal to zero (cf. [16]). More precisely, the third (and all higher odd) moments of \( (L_n - E[L_n])/n \) does not tend to zero as \( n \to \infty \).

In view of the above discussion, a less ambitious goal was set, namely that of computing the large deviations of \( L_n \), i.e., \( \Pr[[L_n - E[L_n]] \geq \varepsilon E[L_n]] \) for \( \varepsilon > 0 \). Hennequin [8] used Chebyshev’s inequality to show
that the above probability is $O(1/\epsilon \log^2 n)$. Recently, Rössler [19] showed that this probability is in fact $O(n^{-k})$ for any fixed $k$, and soon after McDiarmid and Hayward [15] used the powerful method of bounded differences to obtain an even better estimate, namely that the tail is approximately equal to $n^{-2k\log\log n}$ (see the comment after Theorem 1 of Section 2).

In this paper, we obtain some new results for the tail probabilities. First of all, we establish an integral equation for the probability density of $\mathcal{C}_n$, and using this we derive a left tail and a right tail of the large deviations of $\mathcal{L}_n$. We demonstrate that the left tail is much thinner (i.e., double exponential) than the right tail, which is roughly exponential.

We establish these results using formal asymptotic methods of applied mathematics such as the WKB method and matched asymptotics. By “formal” we mean that we do not rigorously establish error bounds on the various asymptotic expansions. The main merit of these methods is that they can be used to obtain asymptotic information directly from the underlying equations. Similar asymptotic approaches were used for enumeration problems by Knessl and Keller [13] and Canfield [3].

The paper is organized as follows. In the next section we describe our main findings and compare them with other known results. In Section 3 we derive the integral equation for the asymptotic probability density of $\mathcal{L}_n$. In Section 4 we obtain our large deviations results.

## 2 Formulation and Summary of Results

As before, we let $\mathcal{L}_n$ be the number of key comparisons made when Quicksort sorts $n$ keys. The probability generating function of $\mathcal{L}_n$ becomes

$$
\mathcal{L}_n(u) = \sum_{k=0}^{\infty} \Pr[\mathcal{L}_n = k] u^k = \mathbb{E}[u^{\mathcal{L}_n}].
$$

The upper limit in this sum may be truncated at $k = (n^2)$, since this is clearly an upper bound on the number of comparisons needed to sort $n$ keys.

The generating function in (5) satisfies (2 on the page before) which we repeat below (cf. also [6, 16, 18, 19])

$$
\mathcal{L}_{n+1}(u) = \frac{u^n}{n+1} \sum_{i=0}^{n} \mathcal{L}_i(u) \mathcal{L}_{n-i}(u), \quad \mathcal{L}_0(u) = 1.
$$

Note that $\mathcal{L}_n(1) = 1$ for all $n \geq 0$, and that the probability $\Pr[\mathcal{L}_n = k]$ may be recovered from the Cauchy integral

$$
\Pr[\mathcal{L}_n = k] = \frac{1}{2\pi i} \int_C u^{-k-1} \mathcal{L}_n(u) du.
$$

Here $C$ is any closed loop about the origin.

In Section 3, we analyze (6) asymptotically for $n \to \infty$ and for various ranges of $u$. We use asymptotic methods of applied mathematics, such as the WKB method and matched asymptotics [2, 7]. The most important scale is where $n \to \infty$ with $u - 1 = O(n^{-1})$, which corresponds to $k = \mathbb{E}[\mathcal{L}_n] + O(n) = 2n \log n + O(n)$. Most of the probability mass is concentrated in this range of $k$. As mentioned before, the existence of a limiting distribution of $(\mathcal{L}_n - \mathbb{E}[\mathcal{L}_n])/n$ as $n \to \infty$ was established in [18, 19], though there seems to be little known about this distribution (cf. [4, 6, 8, 15, 21]). Numerical and simulation results in [4, 6] show that
the distribution is highly asymmetric and that the right tail seems much thicker than the left tail. It is also of interest to estimate these tails (cf. [15, 19]), as they give the probabilities that the number of key comparisons will deviate significantly from $E[L_n]$, which is well known to be asymptotically equal to $2n \log n$ as $n \to \infty$ (cf. [8, 16]).

For $u - 1 = w/n = O(n^{-1})$ and $n \to \infty$, we derive in Section 3 the asymptotic expansion

$$L_n(u) = \exp \left( A_n w/n \left( G_0(w) + \frac{\log n}{n} G_1(w) + \frac{1}{n} G_2(w) + o(n^{-1}) \right) \right)$$

where $A_n = E[L_n]$. The leading term $G_0(w)$ satisfies a non-linear integral equation. Indeed, in Section 3 we find that (cf. (49 on page 52))

$$e^{-w} G_0(w) = \int_0^1 e^{2\phi(x)w} G_0(wx) G_0(w-wx) dx$$

$$G_0(0) = 1; \quad G_0'(0) = 0$$

where

$$\phi(x) = x \log x + (1-x) \log(1-x)$$

is the entropy of the Bernoulli$(x)$ distribution. Furthermore, the correction terms $G_1(\cdot)$ and $G_2(\cdot)$ satisfy linear integral equations (cf. (50 on page 52)–(51 on page 52)).

By using (8) in (7 on the page before) and asymptotically approximating the Cauchy integral we obtain

$$\Pr[L_n - E(L_n) = ny] \sim \frac{1}{n} P(y)$$

where

$$P(y) = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} e^{yw} G_0(w) dw,$$

or equivalently $G_0(w) = -\frac{d}{dy} \log \int_{-\infty}^{\infty} e^{yw} P(y) dy$

and $c$ is a constant. Hence, $G_0(w)$ is the moment generating function of the density $P(y)$.

Now, we can summarize our main findings. We establish the results below under the assumptions that $P(y)$ has certain forms as $y \to \pm \infty$ (cf. Section 4).

**Theorem 1** Consider the Quicksort algorithm that sorts $n$ randomly selected keys.

(i) The limiting density $P(y)$ satisfies

$$P(y+1) = \int_0^1 \int_{-\infty}^{\infty} P \left( x + \frac{y - 2\phi(x)}{2(1-x)} \right) P \left( -(1-x)t + \frac{y - 2\phi(x)}{2x} \right) dt dx$$

and

$$\int_{-\infty}^{\infty} P(y) dy = 1; \quad \int_{-\infty}^{\infty} y P(y) dy = 0.$$  

(ii) The left tail of the distribution satisfies

$$\Pr[L_n - E(L_n) \leq ny] \sim \frac{2}{\pi} \frac{1}{\sqrt{2 \log 2 - 1}} \exp \left( -\alpha \exp \left( \frac{\beta - z}{2 - \log^{-1} 2} \right) \right)$$
for $n \to \infty$, and $z = z(n) \to -\infty$ sufficiently slowly, where $\alpha = \frac{2 \log 2 - 1}{\varepsilon \log \gamma} = 0.205021 \ldots$ and $\beta$ is a constant.

(iii) The right tail becomes

$$\Pr[\mathcal{L}_n - \mathbb{E}(\mathcal{L}_n) \geq ny] \sim \frac{C_n}{2\sqrt{\gamma} w_n \sqrt{w_n - 1}} e^{-w_n (w_n - \frac{1}{2} + 2\gamma + \log 2)} \exp \left( -yw_n + \int_1^{w_n} \frac{2e^u}{u} \, du \right)$$

(18)

for $n \to \infty$, and $y = y(n) \to +\infty$ sufficiently slowly. Here $C_n$ is a constant, $\gamma$ is Euler’s constant and $w_n = w_n(y)$ is the solution to

$$y = \frac{2}{w_n} \exp(w_n)$$

(19)

that asymptotically becomes

$$w_n = \log \left( \frac{y}{2} \right) + \log \log \left( \frac{y}{2} \right) + \frac{\log \log(y/2)}{\log(y/2)} (1 + o(1))$$

(20)

for $y \to \infty$ (cf. (89 on page 60) in Section 4).

Finally, we relate our results for the tails to those of McDiarmid and Hayward [15]. These authors showed that

$$\Pr[|\mathcal{L}_n - \mathbb{E}(\mathcal{L}_n)| > \varepsilon \mathbb{E}(\mathcal{L}_n)] = \exp[-2\varepsilon \log n (\log \log n - \log(1/\varepsilon) + O(\log \log \log n)),]$$

(21)

which holds for $n \to \infty$ and $\varepsilon$ in the range

$$\frac{1}{\log n} < \varepsilon \leq 1.$$  

(22)

As pointed out in [15], this estimate is not very precise if, say, $\varepsilon = O(\log \log n / \log n)$.

From Theorem 1 we conclude that (since the right tail is much thicker than the left tail)

$$\Pr[|\mathcal{L}_n - \mathbb{E}(\mathcal{L}_n)| \geq ny] \sim C_k(y) e^{\Phi(y)}, \quad y \to \infty$$

(23)

where $C$ is a constant and

$$\Phi(y) = -yw_n + \int_1^{w_n} \frac{2e^u}{u} \, du, \quad y = \frac{2e^{w_n}}{w_n},$$

(24)

$$k(y) = \frac{e^{-w_n^2} w_n \log(w_n - 1)}{w_n \sqrt{w_n - 1}}.$$  

We have not been able to determine the upper limit on $y$ for the validity of (23). However, it is easy to see that (23) reduces to (21) if we set $y = \varepsilon \mathbb{E}(\mathcal{L}_n)/n = 2\varepsilon \log n + \varepsilon(2\gamma - 4) + O(\varepsilon \log(n)/n)$ and use (20) to approximate $w_n$, as $y \to \infty$. This yields

$$-yw_n + \int_1^{w_n} \frac{2e^u}{u} \, du = y \left[ -\log \left( \frac{y}{2} \right) - \log \log \left( \frac{y}{2} \right) + 1 + o(1) \right]$$

(25)

which agrees precisely with the estimate (21), and also explicitly identifies the $O(\log \log \log n)$ error term.

This suggests that (23) applies for $y$ as large as $2 \log n$, though it cannot hold for $y$ as large as $n/2$ in view of the fact that $\Pr[\mathcal{L}_n = k] = 0$ for $k > \binom{n}{2}$. An important open problem is obtaining an accurate numerical approximation to the constant $C$. This would likely involve the numerical solution of the integral equation for $G_0(w)$. 

Quicksort algorithm again revisited
3 Analysis of the Generating Function for \( n \to \infty \)

We study (6 on page 45) asymptotically, for various ranges of \( n \) and \( u \), namely: (i) \( u \to 1 \) with \( n \) fixed; (ii) \( w \equiv n(u-1) \) fixed when \( n \to \infty \) and \( u \to 1 \); (iii) \( w \to \pm \infty \); and (iv) \( u < 1 \) or \( u > 1 \). We study these cases below.

A. CASE \( n \) FIXED AND \( u \to 1 \)

First we consider the limit \( u \to 1 \) with \( n \) fixed. Then using the Taylor expansion

\[
L_n(u) = 1 + A_n(u-1) + B_n(u-1)^2 + O((u-1)^3)
\]

we find from (6 on page 45) that \( A_n = L'_n(1) \) and \( B_n = L''_n(1)/2 \) satisfy the linear recurrence equations

\[
A_{n+1} = n + \frac{1}{n+1} \sum_{i=0}^{n} [A_i + A_{n-i}] = n + \frac{2}{n+1} \sum_{i=0}^{n} A_i; \quad A_0 = 0,
\]

\[
B_{n+1} = \left( \frac{n}{2} \right) + \frac{2n}{n+1} \sum_{i=0}^{n} A_i + \frac{1}{n+1} \sum_{i=0}^{n} [2B_i + A_i A_{n-i}]; \quad B_0 = 0.
\]

These are easily solved using either generating functions, or by multiplying (27) and (28) by \( n+1 \) and then differencing with respect to \( n \). The final result is (cf. [14, 16])

\[
A_n = 2(n+1)H_n - 4n
\]

\[
B_n = 2(n+1)^2H_n^2 - (8n+2)(n+1)H_n + \frac{n}{2} (23n+17) - 2(n+1)^2H_n^{(2)}.
\]

Here \( H_n = 1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{n} \) is the harmonic number, and \( H_n^{(2)} = \sum_{k=1}^{n} k^{-2} \) is the harmonic number of second order. In terms of \( A_n \) and \( B_n \), the mean and variance of \( L_n \) are given by

\[
\mathbb{E}[L_n] = A_n = 2(n+1)H_n - 4n
\]

\[
\text{Var} [L_n] = L''_n(1) + [L'_n(1)]^2 = 2B_n + A_n - A_n^2
\]

\[
= 7n^2 - 2(n+1)H_n + 13n - 4(n+1)^2H_n^{(2)}.
\]

Asymptotically, for \( n \to \infty \), we obtain

\[
A_n = 2n \log n + (2\gamma - 4)n + 2 \log n + 2\gamma + 1 + \frac{5}{6}n^{-1} + O(n^{-2})
\]

\[
B_n - \frac{1}{2} \frac{A_n^2}{A_n} \equiv C_n = \left( \frac{7}{2} - \frac{\pi^2}{3} \right) n^2 - 2n \log n + n \left( \frac{21}{2} - 2\gamma - \frac{2}{3} \pi^2 \right) + o(n).
\]

These expressions will be used in order to asymptotically match the expansion for \( u \to 1 \) and \( n \) fixed, to those that will apply for other ranges of \( n \) and \( u \). Since it is well known that the \( l \)th moment of \( L_n - \mathbb{E}[L_n] \) is of order \( O(n^l) \) as \( n \to \infty \), all terms in the series (26) will be of comparable magnitude when (roughly) \( u = 1 = O(n^{-1}) \) and \( n \to \infty \). If we view (26) as an asymptotic series for \( n \) fixed and \( u \to 1 \), then it will cease to be valid when \( n = O((u-1)^{-1}) \), which motivates the analysis that follows.
B. Case \( w \equiv n(u - 1) \) Fixed When \( n \to \infty \) And \( u \to 1 \)

Next we consider the limit \( u \to 1, \ n \to \infty \) with \( w \equiv n(u - 1) \) held fixed. This scaling is necessary to obtain a non–trivial limiting problem. We define \( G(\cdot) \) by

\[
L_n(u) = \exp\left(A_n w/n\right) G(w; n) = e^{A_n(u-1)} G(n(u - 1); n).
\]

With this change of variables, we rewrite (6 on page 45) as

\[
\exp\left(A_n+1 w/n\right) \times G(w + \frac{w}{n} n + 1) = \frac{(1 + w/n)^n}{n + 1}
\]

\[
\times \left\{ \sum_{i=m}^{n-m} \exp\left(A_i \frac{w}{n} + A_{n-i} \frac{w}{n}\right) G\left(w \frac{i}{n}; i\right) G\left(w \left(1 - \frac{i}{n}\right); n - i\right)
\right.
\]

\[
+ 2 \sum_{i=0}^{m-1} \exp\left(A_i \frac{w}{n} + A_{n-i} \frac{w}{n}\right) \left(1 + C_i \frac{w^2}{n^2} + \cdots\right) G\left(w \left(1 - \frac{i}{n}\right); n - i\right)
\]

where \( C_i = B_i - \frac{1}{2} A_i^2 \). Here we have broken up the sum in (6 on page 45) into the three ranges \( 0 \leq i \leq m - 1 \), \( m \leq i \leq n - m \), and \( n - m + 1 \leq i \leq n \), and used the symmetry \((i \to n - i)\) of the summand. We expect (26 on the preceding page) to also be valid for large values of \( n \), as long as \( n(u - 1) \to 0 \) as \( n \to \infty \). Thus, for \( 0 \leq i \leq m - 1 \) we replaced \( L_i(u) \) in the sum by the approximation (26 on the page before). The integer \( m \) may be chosen arbitrarily, since the right side of (36) must ultimately be independent of \( m \). For now we assume that \( m \to \infty \) but \( m/n \to 0 \) as \( n \to \infty \). For \( n \) large we have (cf. (33 on the page before))

\[
\frac{A_i}{n} + \frac{A_{n-i}}{n} = \frac{2 \left(i \log \left(\frac{i}{n}\right) + \left(1 - \frac{i}{n}\right) \log \left(1 - \frac{i}{n}\right)\right)}{n} + 2 \log \left(\frac{i}{n} \left(\frac{i}{n} - \frac{1}{n}\right)\right) + \frac{3}{n} + o(n^{-1})
\]

with which we rewrite (36) as

\[
(n + 1)e^{-w} \times \left(1 + \frac{w^2}{2n} + O(n^{-2})\right) G\left(w + \frac{w}{n} n + 1\right)
\]

\[
= \sum_{i=m}^{n-m} e^{2\phi(i/n)w} \left(1 + w \left(\frac{2}{n} \psi \left(\frac{i}{n}\right) + \frac{3}{n}\right) + O(n^{-2}, n^{-1} m^{-1})\right)
\]

\[
\times G\left(w \frac{i}{n}; i\right) G\left(w \left(1 - \frac{i}{n}\right); n - i\right)
\]

\[
+ 2 \sum_{i=0}^{m-1} \left(1 + A_i \frac{w}{n} + O(B_i n^{-2})\right) \exp\left((A_{n-i} - A_{n+1}) \frac{w}{n}\right)
\]

\[
\times G\left(w \left(1 - \frac{i}{n}\right); n - i\right)
\]

where

\[
\phi(x) = x \log x + (1 - x) \log(1 - x)
\]

\[
\psi(x) = \log[x(1 - x)].
\]

We now evaluate the two sums in (38) asymptotically and show that when the two results are added, the dependence on \( m \) disappears.
so we use this form from the beginning. Note that

\[ G(a) = \sum_{n=0}^{\infty} a^n/n! \]

where \( a_j(n) \) is an asymptotic sequence as \( n \to \infty \), i.e., \( a_{j+1}(n)/a_j(n) \to 0 \) as \( n \to \infty \). The appropriate sequence is determined by balancing terms in \((38)\) on the page before). This will eventually yield

\[ a_1(n) = \frac{\log n}{n}; \quad a_2(n) = \frac{1}{n} \]

so we use this form from the beginning. Note that \( G_0(w) \) is the moment generating function of the limiting density of \((L_n - E[L_n])/n\), which is discussed in [19]. The conditions \((40)\) imply that

\[
\begin{align*}
G_0(0) &= 1; \quad G_1(0) = G_2(0) = \cdots = 0 \quad (43) \\
G'_0(0) &= G'_1(0) = G'_2(0) = \cdots = 0. \quad (44)
\end{align*}
\]

We consider the first sum in \((38)\) on the page before), which we denote by \( S_1 = S_1(n;m) \). Using \((41), (42)\) and the Euler-MacLaurin formula we obtain

\[
S_1 = \sum_{i=n}^{n+m} e^{\varphi(i/n)w} \left[ 1 + w \left( \frac{2}{n} \frac{\varphi(i/n)}{i/n} + \frac{3}{n} \right) + o(n^{-1}) \right] \\
\times \left\{ G_0 \left( w \frac{i}{n} \right) G_0 \left( w \left( 1 - \frac{i}{n} \right) \right) + G_0 \left( w \frac{i}{n} \right) \frac{\log(n-i)}{n-i} G_1 \left( w \left( 1 - \frac{i}{n} \right) \right) \\
+ \frac{G_0 \left( w \left( 1 - \frac{i}{n} \right) \right) \log \frac{i}{n}}{i} G_1 \left( w \frac{i}{n} \right) + G_0 \left( w \frac{i}{n} \right) \frac{1}{n} G_2 \left( w \left( 1 - \frac{i}{n} \right) \right) \\
+ \frac{G_0 \left( w \left( 1 - \frac{i}{n} \right) \right) \frac{1}{i} G_2 \left( w \frac{i}{n} \right) + \cdots \right\} \\
= n \int_{m/n}^{1-m/n} e^{\varphi(x)w} G_0(w) G_0(w - wx) dx + e^{2\varphi(m/n)w} G_0 \left( \frac{m}{n} \right) G_0 \left( w \left( 1 - \frac{m}{n} \right) \right) \\
+ w \int_{m/n}^{1-m/n} [2\varphi(x) + 3] e^{2\varphi(x)w} G_0(w) G_0(w - wx) dx \\
+ \int_{m/n}^{1-m/n} \log \frac{\log(n-1)}{1-x} e^{2\varphi(x)w} G_0(w) G_1(w - wx) dx \\
+ \int_{m/n}^{1-m/n} \log \frac{x}{x} e^{2\varphi(x)w} G_0(w) G_1(w) dx \\
+ \int_{m/n}^{1-m/n} \frac{1}{1-x} e^{2\varphi(x)w} G_0(w) G_2(w - wx) dx \\
+ \int_{m/n}^{1-m/n} \frac{1}{x} e^{2\varphi(x)w} G_2(w) G_0(w - wx) dx + o(1).
\]

We note that all the integrals remain finite as \( m/n \to 0 \), in view of \((43)\) and \((44)\). However, if we were to consider higher order terms in the expansion \((41)\), which would involve terms of order \( n^{-2} \) and \( n^{-3} \), then
the corresponding higher order terms in (45 on the page before) would involve integrands not integrable over [0,1]. It then becomes essential that we integrate only over the range \([m/n, 1 - m/n]\) and consider the contribution from the second sum \(S_2 = S_2(n; m)\) in (38 on page 49). We can further simplify \(S_1\) by evaluating each term in the limit \(m/n \to 0\), which we assumed to be true. We have

\[
T_{11} \equiv \int_{m/n}^{1-m/n} e^{2\theta(x)w} G_0(wx)G_0(w-wx)dx
\]

\[
= \int_0^1 e^{2\theta(x)w} G_0(wx)G_0(w-wx)dx - 2\int_0^{m/n} e^{2\theta(x)w} G_0(wx)G_0(w-wx)dx
\]

\[
= \int_0^1 e^{2\theta(x)w} G_0(wx)G_0(w-wx)dx - 2\int_0^{m/n} [1 + 2w(x\log x - x) + O(x^2)]
\]

\[
\times [1 + O(x^2)] [G_0(w) - wG_0(w) + O(x^2)] dx
\]

\[
\sim \int_0^1 e^{2\theta(x)w} G_0(wx)G_0(w-wx)dx
\]

\[
- 2G_0(w) \left[ \frac{m}{n} + 2w \left( \frac{m^2}{2n^2} \log \left( \frac{m}{n} \right) - \frac{3m^2}{4n^2} \right) \right] + \frac{m^2}{n^2} w^2 G_0(w);
\]

\[
T_{12} \equiv 2\int_{m/n}^{1-m/n} \log n + \log x \frac{e^{2\theta(x)w} G_0(w-wx)G_1(wx)dx}{x}
\]

\[
\sim 2\int_0^1 \log n + \log x \frac{e^{2\theta(x)w} G_0(w-wx)G_1(wx)dx - 2\frac{m}{n} (\log n) G_1(w)}{x};
\]

and

\[
T_{13} \equiv 2\int_{m/n}^{1-m/n} \frac{1}{x} e^{2\theta(x)w} G_2(wx)G_0(w-wx)dx
\]

\[
\sim 2\int_0^1 \frac{1}{x} e^{2\theta(x)w} G_2(wx)G_0(w-wx)dx - 2\frac{m}{n} G_2(w).
\]

Thus \(S_1\) simplifies to

\[
S_1 = n\int_0^1 e^{2\theta(x)w} G_0(wx)G_0(w-wx)dx + G_0(w)
\]

\[
+ \left[ 2\psi(x) + 3 \right] e^{2\theta(x)w} G_0(wx)G_0(w-wx)dx
\]

\[
+ 2\int_0^1 \log n + \log x \frac{e^{2\theta(x)w} G_0(w-wx)G_1(wx)dx}{x}
\]

\[
+ 2\int_0^1 \frac{1}{x} e^{2\theta(x)w} G_0(w-wx)G_2(wx)dx
\]

\[
\left\{ -2mG_0(w) + \frac{m^2}{n} G_1(w) - \frac{2m^2}{n} wG_0(w) \left[ \log \left( \frac{m}{n} \right) - \frac{3}{2} \right]
\]

\[
- 2\frac{m}{n} (\log n) G_1(w) - 2\frac{m}{n} G_2(w) \right\} + \ldots
\]

where we have grouped the terms involving \(m\) inside the "\{ \}". The error term in (46) approaches zero as \(n \to \infty\).

Now we consider the second sum \(S_2\) in (38 on page 49). Using \(A(n - i) - A(n + 1) \sim -(i + 1)A'(n) \sim -(i + 1)(2\log n + 2\gamma - 2)\), we obtain

\[
S_2 \sim 2 \sum_{i=0}^{m-1} \left[ 1 + A_i \frac{w}{n} \right] \left[ 1 - \frac{w}{n} (i + 1)(2\log n + 2\gamma - 2) \right] \tag{47}
\]
arguments.

This eliminates the trivial solution $G_0(w) = 0$ and satisfies the normalization $G_0(0) = 1$. Using (52) in (49) and noting that $\int_0^1 [2\phi(x) + 1]dx = 0$, we see that $g_1$ remains arbitrary, and then we can easily calculate $g_j$ for $j \geq 2$ in terms of $g_1$. But, (44 on page 50) forces $g_1 = 0$ and then all the Taylor coefficients in (52) are
uniquely determined. They may be evaluated from the recursion

\[
\left(1 - \frac{2}{n+1}\right) g_n = \sum_{i=1}^{n-1} B(i, n-i, 0) g_i g_{n-i} + \sum_{\ell=0}^{n-1} \sum_{i=0}^{\ell} B(i, \ell - 1, n - \ell) g_i g_{\ell - i}
\]  

(53)

for \( n \geq 2 \) where

\[
B(i, j, k) = \int_0^1 x^j (1-x)^i \frac{1}{k!} [2\phi(x) + 1]^k dx.
\]

(54)

In particular, \( g_2 = \frac{\pi^2}{6} - \frac{\pi^2}{4} \).

Next we consider the equations (50 on the page before) and (51 on the preceding page) for the correction terms \( G_1 \) and \( G_2 \). These are linear, Fredholm integral equations of the second kind. Their solutions may also be constructed as Taylor series in \( w \). In view of (43 on page 50) and (44 on page 50) we must have

\[
G_0(w) \sim 1 + \alpha_0 w^2;
\]

\[
G_1(w) \sim \beta_0 w^2;
\]

\[
G_2(w) \sim \gamma_0 w^2,
\]

as \( w \to 0 \), where we have already computed \( \alpha_0 = g_2 \). Given \( \beta_0 \), we can easily compute the higher order Taylor coefficients of \( G_1(w) \) from (50 on the page before), in terms of the (now uniquely determined) Taylor coefficients of \( G_0(w) \). However, the constant \( \beta_0 \) cannot be determined solely from (50 on the preceding page), (43 on page 50) and (44 on page 50). To fix \( \beta_0 \) we use the principle of asymptotic matching. We require that expansions (26 on page 48) and (35 on page 49) (with (41 on page 50)) agree in some intermediate limit, where \( u \to 1, n \to \infty \) and \( n(u-1) \to 0 \). Then the behavior of (26 on page 48) as \( n \to \infty \) must agree with the behavior of (35 on page 49) (with (41 on page 50)) as \( w \to 0 \). Writing (26 on page 48) as \( L_n(u) = \exp[A_n(u-1)][1 + C_n(u-1)^2 + O((u-1)^3)] \) the matching condition becomes

\[
1 + C_n(u-1)^2 + \cdots \bigg|_{n \to \infty} \sim G_0(w) + \frac{\log n}{n} G_1(w) + \frac{1}{n} G_2(w) + \cdots \bigg|_{w \to 0}.
\]

(55)

Setting \( u - 1 = w/n \), using (34 on page 48), and noting that the right side of (55) is \( 1 + n^{-2}[\alpha_0 n^2 + \beta_0 (\log n) n + \gamma_0 n^2] w^2 \), we obtain

\[
\beta_0 = -2; \quad \gamma_0 = \frac{21}{2} - 2 \gamma - \frac{2}{3} \pi^2.
\]

(56)

Now consider equation (51 on the preceding page) in the limit \( w \to 0 \). We write (50 on the page before) abstractly as \( TG_1 = 0 \) where \( T \) is the linear integral operator in (50 on the preceding page). Then (51 on the page before) may be written as \( TG_2 = f(G_0, G_1) \) where \( f \) is a known function of the first two terms. Since \( TG_1 = 0 \) has a non-zero solution (made unique by the condition \( \beta_0 = -2 \)), we expect that \( TG_2 = f \) will have a solution only if a solvability condition is met. To obtain this solvability condition we expand (51 on the preceding page) as \( w \to 0 \). Obviously (51 on the page before) is satisfied as \( w \to 0 \), and, since

\[
\int_0^1 \frac{1}{2} \psi(x) + 3 \, dx = -1, \quad (51 \text{ on the preceding page}) \text{ also holds to order } O(w).
\]

Comparing \( O(w^2) \) terms in
(51 on page 52) using (55 on the preceding page) gives

\[ 1 + 2\alpha_0 = -\frac{1}{2}\beta_0 - 3 + 4 \int_0^1 \phi(x)\psi(x)\,dx \]

(57)

and thus \( \beta_0 = -2 \), which regains the result we obtained by using asymptotic matching. Note, however, that this argument required that we derive the equation satisfied by \( G_2(w) \) in order to uniquely specify the previous term \( G_1(w) \). In contrast, asymptotic matching made no use of (51 on page 52). Presumably, by deriving the equation for the next term \( G_3(w) \) in (41 on page 50) and examining its solvability condition, we would have an alternate way of computing \( \gamma_0 \). Given \( \beta_0 \) and \( \gamma_0 \), we can easily obtain the Taylor expansions of \( G_1 \) and \( G_2 \) from (50 on page 52) and (51 on page 52).

To summarize, we have obtained the expansion (35 on page 49), with (41 on page 50)-(44 on page 50), (49 on page 52)-(51 on page 52) and (56 on the preceding page), for the scaling \( n \to \infty \), \( u \to 1 \) with \( n(u - 1) = w \) fixed. We have not been able to explicitly solve these integral equations. However, we can derive some approximate formulas in the limits \( w \to \pm \infty \), and these may be used to obtain approximations to the tail probabilities of the Quicksort distribution.

C. Case \( w \equiv n(u - 1) \to \pm \infty \)

We shall only examine the leading term \( G_0 \), and we first consider the limit \( w \to -\infty \). As \( w \to -\infty \), the “kernel” \( \exp[2w\phi(x)] \) in (49 on page 52) is sharply concentrated near \( x = 1/2 \), and behaves as a multiple of \( \phi(x) \). Thus we treat (49 on page 52) as a Laplace type integral (cf. [10]).

Assuming that \( G_0(w) \) has a weak (e.g., algebraic) dependence on \( w \), we approximate the right side of (49 on page 52) by Laplace’s method, which (to leading order) yields the functional equation

\[ e^{-w} G_0(w) \approx \left[ G_0 \left( \frac{w}{2} \right) \right]^2 \frac{\pi}{-4w} e^{-2w\log 2}, \quad w \to -\infty. \]

(58)

But, if \( G_0 \) varies weakly with \( w \), then the exponential orders of magnitude of the right and left sides of (58) do not agree. In order to get agreement, we would need \( G_0(w) \) to vary much more rapidly as \( w \to -\infty \), of the order \( \exp[O(w\log(-w))] \). But this then contradicts the assumption used to obtain (58). Therefore, we return to (49 on page 52) and allow more rapid variation of \( G_0 \). Specifically, we assume that as \( w \to -\infty \)

\[ G_0(w) \sim e^{\alpha_1 w\log(-w) + \beta_0 w} (-w)^{\gamma_1} \delta_1. \]

(59)

Using (59) in (49 on page 52) yields

\[ e^{-w} (-w)^{\gamma_1} \delta_1 \sim \delta_1 \int_0^1 \phi(x) e^{\theta(x)(2+\alpha_1)w} \,dx. \]

(60)

If \( 2 + \alpha_1 > 0 \) we again use Laplace’s method to approximate the integral, thus obtaining

\[ e^{-w} \sim \delta_1 \left( \frac{1}{4} \right)^{\gamma_1} (-w)^{-\frac{1}{2}} \frac{\pi}{\sqrt{2(2 + \alpha_1)}} e^{-(\alpha_1+2)(\log 2)w}. \]

(61)

Hence, we must have

\[ \alpha_1 = -2 + \frac{1}{\log 2}; \quad \gamma_1 = \frac{1}{2}; \quad \delta_1 = \frac{2\sqrt{2}}{\sqrt{\pi \log 2}}. \]

(62)
and $\beta$ remains arbitrary. Since the solution of (49 on page 52) is not unique, we can never determine $\beta$ using only this integral equation. We thus have

$$G_0(w) \sim \frac{2^{\sqrt{2}}}{\sqrt{\pi \log 2}} \sqrt[w]{\exp\left[\beta w + \left(1 - \log 2 - 2\right) w \log(-w)\right]} \quad w \to -\infty. \quad (63)$$

By computing higher order terms in the expansion of the integral in (49 on page 52), we can extend (59 on the page before) and (63) to an asymptotic series in powers of $w^{-1}$. To fix $\beta$, we must use the condition in (43 on page 50) and (44 on page 50), and this probably requires a numerical solution of (49 on page 52). By comparing this numerical solution to (49 on page 52) for large, negative $w$ to (63), we can obtain an approximation to $\beta$.

Now consider (49 on page 52) in the limit $w \to +\infty$. Then $\exp[2w\phi(x)]$ is concentrated near the endpoints $x = 0$ and $x = 1$. We assume that $G_0(w)$ has an asymptotic expansion in the WKB form [7]:

$$G_0(w) \sim K(w) \exp[\Psi(w)]. \quad (64)$$

The major contribution to the integral will come from where $x, 1 - x = o(w^{-1})$. Thus we use the Taylor series $G_0(wx) = 1 + O((wx)^2)$, and (64) to approximate $G_0(w - wx)$. This yields

$$K(w) e^{\Psi(w) - w} \sim 2 \int_0^{1/2} [1 + 2w\phi(x) + O((w^2\phi^2(x))] [1 + O((wx^2)] K(w - wx) e^{\Psi(w - wx)} dx$$

$$\sim 2K(w) e^{\Psi(w)} \int_0^{1/2} e^{-w\Psi(x)} dx. \quad (65)$$

If furthermore $\Psi(\cdot)$ is such that $w\Psi'(w) \to \infty$ as $w \to \infty$, then (65) yields (after a slight rearrangement)

$$w\Psi'(w) \sim 2e^w$$

and hence we define

$$\Psi(w) = 2 \int_0^w \frac{e^u}{u} du. \quad (66)$$

Note that (66) is consistent with $w\Psi'(w) \to \infty$ and shows that $G_0$ grows very rapidly (as a double exponential) as $w \to +\infty$. We note that the asymptotic expansion of the integrand in (65) is only valid for $x = o(w^{-1})$, but the major contribution to the integral turns out to be from $x = O(e^{-w})$, which is certainly $o(w^{-1})$. To obtain the next term $K(w)$, we refine the expansion (65) to

$$K(w) e^{\Psi(w) - w} = 2 \int_0^{1/2} [1 + 2w\phi(x) + O((w^2\phi^2(x))] [1 + O((wx^2)]$$

$$\times \left[K(w) - wxK'(w) + O(w^2x^2\Psi''(w))\right]$$

$$\times \exp\left(\Psi(w) - w\Psi'(w)x + \frac{1}{2}w^2\Psi''(w)x^2 + O(w^3\Psi''(w)x^3)\right) dx.$$

For $x$ small we have $2w\phi(x) = 2w(x \log x - x + O(x^2))$ and if $x = O(e^{-w})$ then $w^2x^2 = O(w^2e^{-2w})$ and $w^3x^3\Psi''(w) = O(w^2e^{-2w})$. Setting $x = \eta e^{-w}/2$ we have

$$\exp\left[\frac{1}{2}x^2w^2\Psi''(w)\right] = 1 + \frac{1}{4}\eta^2(w - 1)e^{-w}[1 + o(1)].$$
Thus (67 on the preceding page) becomes, after cancelling the common factor \(\exp[\Psi(w)]\),

\[
e^{-w}K(w) = e^{-w} \int_0^\infty e^{-\eta}d\eta + K(w) \int_0^\infty e^{-\eta} \left[ \frac{1}{4} e^{-w} \eta^2 (w-1) + w e^{-w} \eta \left(-w + \log \left(\frac{\eta}{2}\right) - 1\right) \right] d\eta - K'(w) w e^{-w} \int_0^\infty \frac{1}{2} \eta e^{-\eta} d\eta + O(e^{-2w}K(w)w^n)\]

(68)

for some constant \(\alpha\). To leading order (68) is obviously satisfied and then collecting terms that are of order \(O(e^{-w})\) as \(w \to \infty\) (modulo some algebraic factors) we obtain the following differential equation

\[
\frac{w}{2} \frac{K'(w)}{K(w)} = \int_0^\infty \left[ \frac{1}{4} \eta^2 e^{-\eta}(w-1) + w \eta e^{-\eta} \left(-w + \log \left(\frac{\eta}{2}\right) - 1\right) \right] d\eta
\]

(69)

and thus

\[
\frac{K'(w)}{K(w)} = -2w + 1 - 2\gamma - 2 \log 2 - \frac{1}{w}.
\]

(70)

Solving (70) and using the result along with (66 on the page before), we have

\[
G_0(w) \sim C_1 \exp \left( \int_1^w \frac{2e^{\eta}}{\eta} du - \eta^2 + (1 - 1 - 2\gamma - 2 \log 2 \eta - 1) \right) \frac{1}{w}.
\]

(71)

Here \(C_1\) is an undetermined constant and we have chosen the lower limit on the integral in (66 on the preceding page) as one. An alternate choice would only change \(C_1\), which we cannot determine using only the integral equation (49 on page 52).

Our analysis shows that as \(w \to +\infty\), the nonlinear equation (49 on page 52) may be approximated by a linear one. To fix \(C_1\) it would seem that we will again need an accurate numerical solution to (49 on page 52).

We have thus obtained formal asymptotic results as \(w \to \pm\infty\) for the solution to (49 on page 52). Using our procedure we can derive full asymptotic series in these limits, but the constants \(\beta\) and \(C_1\) will remain undetermined.

In Section 4, we will use our results for \(G_0(w)\) to obtain asymptotic expansions for the limiting density \(P(y)\) as \(y \to \pm\infty\).

D. CASE \(u < 1\) OR \(u > 1\)

We next study (6 on page 45) for \(n \to \infty\) but for fixed \(u > 1\) or \(u < 1\). First we assume that \(0 < u < 1\). Note that \(u\) appears in (6 on page 45) only as a parameter. We assume an expansion of the form

\[
L_n(u) \sim e^{A(u) n \log n + B(u) n + C(u)} D(u)
\]

(72)

for \(n \to \infty\) and \(u < 1\). The major contribution to the sum in (6 on page 45) will come from the midpoint \(i \approx n/2\). Using (72) in (6 on page 45) and noting that \((n+1) \log (n+1) = n \log n + \log n + 1 + O(n^{-1})\) and \(i \log i + (n-i) \log (n-i) = n \log n - \log n + 2 \log 2 + 2n^{-1} (i-n/2)^2 + O(n^{-2} (i-n/2)^3)\), we obtain

\[
e^{A(u) n \log n + B(u) n + C(u)} D(u) \sim D^2 \left(\frac{n}{2}\right)^C e^{B(u) \frac{n}{2}} e^{A(u) \log n} e^{-A(u) \log 2} \times \sum_{i=0}^{n} \exp \left( -\frac{2}{n} |B| (i-n/2)^2 \right)
\]
for $A < 0$. The sum is asymptotically equal to $\sqrt{n\pi/2|A|}$, and thus

$$A = \frac{\log u}{\log 2}, \quad C = \frac{1}{2} + \frac{\log u}{\log 2},$$

$$D = 2e^Bu^2 \sqrt{-\frac{2\log u}{\pi\log 2}} \exp\left(\frac{\log u}{\log 2}\right)$$

and $B = B(u)$ remains arbitrary.

Some further information may be obtained by asymptotically matching (72 on the preceding page) to the expansion valid for $n \to \infty, u - 1 = O(n^{-1})$. In the intermediate limit where $u \to 1, n \to \infty$ and $n(u - 1) \to -\infty$, we use (63 on page 55) with $w = n(u - 1)$ to get

$$e^{A_n(u-1)}G_0(w) \sim e^{2(u-1)n\log n}e^{[2(1-u)n(u-1)]} \frac{2\sqrt{2}}{\sqrt{\pi\log 2}} \exp^{bn(u-1)}$$

$$\times \sqrt{n(1-u)}\exp\left\{\left(\frac{1}{\log 2} - 2\right) n(u - 1)[\log n + \log(1 - u)]\right\}.$$

As $u \uparrow 1$, (72 on the preceding page) and (73) yields

$$\exp\left\{\left[\frac{u - 1}{\log 2} + O((u - 1)^2)\right] n\log n + Bn\right\} n^{1/2} 2e^B \sqrt{\frac{2(1-u)}{\pi\log 2}}$$

and these two expressions agree provided that as $u \uparrow 1$

$$B(u) \sim \left(\frac{1}{\log 2} - 2\right) (u - 1)\log(1 - u) + (2\gamma - 4 + \beta)(u - 1), \quad u \to 1.$$  

(74)

This relates the behavior of $B(u)$ as $u \uparrow 1$ to the constant $\beta$ in (63 on page 55).

Now consider $n \to \infty$ with $u > 1$. The dominant contribution in the sum (6 on page 45) now comes from the terms with $i = 0$ and $i = n$. Thus

$$L_{n+1}(u) = \frac{u^n}{n+1}[2L_0(u)L_n(u) + 2L_1(u)L_{n-1}(u) + \cdots] \sim \frac{2u^n}{n+1} L_n(u)$$

(75)

and

$$L_n(u) \sim u^{\left(\frac{2}{n}\right)} k_1(u); \quad n \to \infty, u > 1$$

(76)

where $k_1(u)$ is an undetermined function. Since for $u \to \infty$ and all $n \geq 2, L_n(u) \sim u^{\left(\frac{2}{n}\right)}2^n/[4n!]$, we have $k_1(u) \to 1/4$ as $u \to \infty$.

We examine asymptotic matching between the expansions for $u > 1$ and $u - 1 = O(n^{-1})$. If (76) matches to $e^{A_n(u-1)}G_0(w)$ then (71 on the page before) would agree with the expansion of (76) as $u \downarrow 1$. However this cannot be true as the dominant exponential term in (71 on the page before) is

$$O\left[\exp\left(\frac{2e^n}{w}\right)\right] = O\left[\exp\left(\frac{2e^{n(u-1)}}{n(u-1)}\right)\right]$$

(77)

while the dominant term in (76) as $u \to 1$ is

$$O\left[\exp\left(\frac{n^2}{2}(u-1)\right)\right].$$

(78)
This suggests that yet another expansion is needed on some scale where \( n \to \infty \) and \( u \downarrow 1 \) with \( n(u-1) \to +\infty \). By comparing (77 on the page before) to (78 on the preceding page), this new scale is likely to be

\[
w = n(u - 1) = \log n + 2 \log \log n + O(1). \tag{79}\]

With this scaling both (77 on the page before) and (78 on the preceding page) are \( \exp[O(n \log n)] \). We have not examined this intermediate scale in any detail. However, we would guess that with (79), the approximation of (6 on page 45) will involve retaining an infinite number of terms in this sum (rather than just the 2 terms in (75 on the page before)), but not approximating the sum by an integral, as was possible when \( u - 1 = O(n^{-1}) \).

To summarize this section, we have analyzed (6 on page 45) in various asymptotic limits. These include (i) \( u \uparrow 1, n \) fixed; (ii) \( u \to 1, n \to \infty, n(u-1) = w \) fixed; (iii) \( w \to \pm \infty; (iv) 0 < u < 1, n \to \infty; \) and (v) \( u > 1, n \to \infty \). In the next section, we use these results to obtain information about the distribution \( \Pr[\mathcal{L}_n = k] \).

### 4 Tails of the Limiting Distribution

Using the approximation (35 on page 49) for \( u - 1 = O(n^{-1}) \), we obtain

\[
\Pr[\mathcal{L}_n - \mathbb{E}(\mathcal{L}_n) = ny] = \frac{1}{2\pi i} \int_{C} z^{-[ny+A_0+1]} L_n(z) dz. \tag{80}\]

\[
\sim \frac{1}{n} \frac{1}{2\pi i} \int_{C} \left(1 + \frac{w}{n}\right)^{-ny-1} e^{-A_0 \log(1+wn/n)+A_0 w/n} G_0(w) dw
\]

\[
\sim \frac{1}{n} \frac{1}{2\pi i} \int_{Br} e^{-yw} G_0(w) dw = \frac{1}{n} P(y)
\]

where \( Br = (c-i\infty, c+i\infty) \) for some constant \( c \), is any vertical contour in the \( w \)-plane. Here we have set \( z = 1 + w/n \) in the integral. It follows that

\[
G_0(w) = \int_{-\infty}^{\infty} e^{wy} P(y) dy \tag{81}\]

so that \( G_0(w) \) is the moment generating function of the density \( P(y) \). In view of (43 on page 50) and (44 on page 50) we have \( \int_{-\infty}^{\infty} P(y) dy = 1 \) and \( \int_{-\infty}^{\infty} yP(y) dy = 0 \).

Observe that, using (35 on page 49), (41 on page 50), and (42 on page 50), we can refine the approximation (80) to

\[
\Pr[\mathcal{L}_n - \mathbb{E}(\mathcal{L}_n) = ny] = \frac{1}{n} \left( P(y) + \frac{\log n}{n} [P_1(y) + P''(y)] + \frac{1}{2} [P_2(y) + P''(y) + (y-2)P''(y)] + o(n^{-1}) \right)
\]

where

\[
P_k(y) = \frac{1}{2\pi i} \int_{Br} e^{-yw} G_k(w) dw \tag{82}\]

for \( k = 1, 2 \).
An integral equation for $P(y)$ can easily be derived from (49 on page 52). We multiply (49 on page 52) by $e^{-wy}/(2\pi i)$ and integrate over a contour $B_r$ in the $w$-plane:

$$
P(y + 1) = \frac{1}{2\pi i} \int_{B_r} e^{-w(y+1)} G_0(w) dw \tag{83}
$$

$$
= \frac{1}{2\pi i} \int_{B_r} \int_0^1 e^{2w\phi(x)} G_0(wx) G_0(w - wx) e^{-wy} dx dw
$$

$$
= \int_0^1 \frac{1}{2\pi i} \int_{B_r} e^{-wy} \int_{-\infty}^\infty P(\xi) e^{w\xi^2} d\xi \int_{-\infty}^\infty P(\eta) e^{(w-w\eta)\eta} d\eta \ e^{2w\phi(x)} dw dx
$$

$$
= \int_0^1 \int_{-\infty}^\infty P(\xi)P(\eta)\delta(y - x\xi - (1 - x)\eta - 2\phi(x)) d\eta d\xi dx
$$

$$
= \int_0^1 \int_{-\infty}^\infty P(\eta) \frac{y - \frac{1 - x}{x} \eta - \frac{2\phi(x)}{x}}{x} \ d\eta dx
$$

$$
= \int_0^1 \int_{-\infty}^\infty \left(x(1 - x) + \frac{y/2 - \phi(x)}{1 - x} \right) P\left(-(1 - x)t + \frac{y/2 - \phi(x)}{x}\right) dt dx,
$$

where we used the well known identity (cf. [1])

$$
\frac{1}{2\pi i} \int_{B_r} e^{-w} dw = \delta(y) \tag{84}
$$

where $\delta(y)$ is Dirac’s delta function. The last expression is precisely (15 on page 46). The solution to this integral equation is not unique: if $P(y)$ is a solution, so is $P(y + c)$ for any $c$.

We study $P(y) = (2\pi i)^{-1} \int_{B_r} e^{-w} G_0(w) dw$ as $y \to \pm\infty$. We argue that the asymptotic expansion of the integral will be determined by a saddle point $w = s(y)$, which satisfies $s(y) \to \pm\infty$ as $y \to \pm\infty$. Thus for $y \to -\infty$, we can use the approximation (63 on page 35) for $G_0(w)$, which yields

$$
P(y) \sim \frac{1}{2\pi i} \int_{B_r} \sqrt{2\pi \log 2} \sqrt{-w} \exp \left[(\beta - y)w + \left(\frac{1}{\log 2} - 2\right) w \log(-w)\right] dw. \tag{85}
$$

This integrand has a saddle point where

$$
\frac{d}{dw} \left[-(\beta - y)w + \left(\frac{1}{\log 2} - 2\right) w \log(-w)\right] = 0
$$

so that

$$
w = -\frac{1}{e} \exp \left[-\frac{y - \beta}{2 - 1/\log 2}\right] \equiv \tilde{w}(y)
$$

which satisfies $\tilde{w}(y) \to -\infty$ as $y \to -\infty$. Then the standard saddle point approximation to (85) yields

$$
P(y) \sim \frac{2\sqrt{2}}{\sqrt{\pi \log 2}} \sqrt{-\tilde{w}} \exp \left[(\beta - y)\tilde{w} + \left(\frac{1}{\log 2} - 2\right) \tilde{w} \log(-\tilde{w})\right]
$$

$$
\times \frac{1}{2\pi i} \int_{B_r} \exp \left[\frac{1}{2\tilde{w}} \left(\frac{1}{\log 2} - 2\right) (w - \tilde{w})^2\right] dw
$$

$$
= \frac{2}{\pi e} \frac{1}{\sqrt{2\log 2 - 1}} \exp \left[\frac{\beta - y}{2 - 1/\log 2} - \frac{2 - 1/\log 2}{e} \exp \left(\frac{\beta - y}{2 - 1/\log 2}\right)\right]
$$

for $y \to -\infty$. Thus, the left tail is very small and the behavior of $P(y)$ as $y \to -\infty$ is similar to that of an extreme value distribution (i.e., double-exponential distribution).
Now take \( y \to +\infty \) and use (71 on page 56) to get

\[
P(y) \sim \frac{1}{2\pi} \int_{Br} C_* \exp \left( \int_1^{w} \frac{2e^u}{u} du \right) \frac{1}{w} e^{-y\sqrt{w^2 + (1-2\gamma-2\log 2)w}} \, dw.
\]  

(87)

The saddle point now satisfies

\[
\frac{d}{dw} \left[ -yw + \int_1^{w} \frac{2e^u}{u} du \right] = 0
\]
or \( y = 2e^w/w \). Let \( w_* = w_*(y) \) be the solution to (19 on page 47) that satisfies \( w_* \to \infty \) as \( y \to \infty \). Then expanding the integrand in (87) about \( w = w_*(y) \) and using the standard saddle point approximation yields

\[
P(y) \sim \frac{C_*}{2\sqrt{2\pi \sqrt[4]{1-w_*}}} \exp \left[ -yw_* + \int_{w_*}^\infty \frac{2e^u}{u} du - w_*^2 - (2\gamma + 2\log 2)w_* \right]
\]
as \( y \to \infty \), from which (18 on page 47) easily follows. Thus for \( y \to \infty \) we have \( P(y) = \exp[O(-y\log y)] \) and hence the right tail is thinner than the right tail of an extreme value distribution. From (19 on page 47) it is easy to show that

\[
w_* = \log \left( \frac{y}{2} \right) + \log \log \left( \frac{y}{2} \right) + \frac{\log \log(y/2)}{\log(y/2)} (1 + o(1)), \quad y \to \infty.
\]

(89)

For fixed \( z \) and \( y \) we have, as \( n \to \infty \),

\[
\Pr[\mathcal{L}_n - E(\mathcal{L}_n) \leq nz] \sim \int_{-\infty}^z P(y)dy
\]

(90)

\[
\Pr[\mathcal{L}_n - E(\mathcal{L}_n) \geq ny] \sim \int_y^{\infty} P(u)du.
\]

(91)

If \( z \to -\infty \) or \( y \to +\infty \), then these integrals may be evaluated asymptotically using (86 on the preceding page) and (88), and we obtain the results (17 on page 46) and (18 on page 47), respectively.

This derivation of the expansions of \( P(y) \) as \( y \to \pm \infty \) has the disadvantage in that it assumes the existence of certain saddle points. However, we can obtain the identical results simply by using the integral equation for \( P(y) \), which we now show.

Let us write (83 on the preceding page) in the form

\[
P(y+1) = \int_0^1 \frac{1}{x(1-x)} \int_{-\infty}^{\infty} P \left( \frac{\xi + y/2 - \Phi(x)}{1-x} \right) P \left( \frac{-\xi + y/2 - \Phi(x)}{x} \right) d\xi dx
\]

(92)

and assume that for \( y \to -\infty \), \( P(y) \) has the form

\[
P(y) \sim de^{\gamma} \exp[-ae^{-by}]
\]

(93)

for some constants \( a, b, c, d \). Using (93) in (92) we find that the major contribution to the double integral will come from \( (x, \xi) = (\frac{1}{2}, 0) \). After scaling \( x = \frac{1}{2}(1 + e^{by/2}) \) and \( \xi = e^{by/2} \eta \) we obtain

\[
de^{\gamma} e^{\xi} \exp[-ae^{-b}e^{-by}] \sim 2e^{by}d^2 \exp[-2ae^{-by}e^{-2b\log 2}]
\]

\[
\times e^{2y} e^{\xi \log 2} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \exp \left[ -v(u(2 \log 2) + 2\eta^2) - 2v\eta(u^2(2 \log 2 - 1) + 2\eta u) \right] du d\eta
\]
Quicksort algorithm again revisited

where \( v = ae^{-2b \log 2} \). The double integral is equal to \( \pi(2v)^{-1} b^{-3/2} (2 - 1/b)^{-1/2} \) and thus the above yields

\[
2e^{-2b \log 2} = e^{-b}, \quad e^v = e^{v(b+2c)}
\]

(94)

\[
de^c = 2d^2 \frac{\pi}{2d} e^{2c \log 2} b^{-3/2} e^{2b \log 2} \left( 2 - \frac{1}{b} \right)^{-1/2}.
\]

We thus have

\[
b = \frac{2 - 1/\log 2}{2 - 1/b}, \quad c = -b, \quad d = 2\frac{a}{\pi} b^{3/2} \sqrt{2 - \frac{1}{b}}
\]

(95)

and \( a \) remains arbitrary. But then (93 on the page before) is equivalent to (86 on page 59) if we identify \( a \) as

\[
a = \frac{2 - 1/\log 2}{e} \exp \left[ \frac{\beta}{2 - 1/\log 2} \right]
\]

(96)

Next we consider \( y \to +\infty \) and write the equation for \( P(y) \) in the form

\[
P(y + 1) = 2 \int_0^{1/2} \frac{1}{1-x} \int_y^\infty P(\eta) P \left( y + \frac{x(\eta - x) - 2F(x)}{1-x} \right) d\eta dx.
\]

(97)

We seek solutions in the WKB form

\[
P(y) \sim G(y) e^{F(y)}, \quad y \to +\infty
\]

(98)

where \( \log G \) varies less rapidly than \( F \). Then (97) may be approximated by

\[
e^{F(y)+F'(y)} [G(y)+G'(y)+\ldots] \left[ 1 + \frac{1}{2} F''(y)+\ldots \right] =
\]

(99)

\[
= 2 \int_0^{1/2} \frac{1}{1-x} \int_y^\infty P(\eta) e^{F(y)} \exp \left\{ \left[ \frac{x(\eta - x) - 2F(x)}{1-x} \right] F'(y) \right\}
\]

\[
\times \left[ G(y) + \frac{x(\eta - x) - 2F(x)}{1-x} G'(y) + \ldots \right] \left[ 1 + \frac{1}{2} \left( \frac{x(\eta - x) - 2F(x)}{1-x} \right)^2 F''(y) + \ldots \right] d\eta dx.
\]

After scaling \( x = \omega/[yF'(y)] \), the leading term in the right side of (99) is \( e^{F(y)} G(y)(-2)/(yF'(y)) \) and hence

\[
e^{F(y)} = -\frac{2}{yF'(y)}
\]

(100)

After some calculation, we obtain the following linear differential equation for \( G \):

\[
G' + \frac{1}{2} F'' G = \frac{G}{yF'} - \frac{2G}{y} [y + \log(-yF')] - \frac{G'}{F'} + \frac{F''}{(F')^2} G
\]

(101)

Equation (100) is a first order non-linear ordinary differential equation for \( F \), which is really just a transcendental equation for \( F' \). Setting \( F'(y) \equiv -w_*(y) \) we have

\[
F(y) = -\int y w_*(t) dt = -\int w_*(y) \left( \frac{e^y}{\zeta} - \frac{e^y}{\zeta^2} \right) d\zeta
\]

(102)

\[
= -yw_* + 2 \int w_* \frac{e^y}{\zeta} d\zeta
\]
where we have used (100 on the preceding page) to change the variable of integration. But then the dominant exponential terms in (88 on page 60) and (98 on the preceding page) agree precisely. To solve (101 on the page before) we change variables $y \leftrightarrow w_*$ and write (101 on the preceding page) as
\[
\frac{G'(y)}{G(y)} = -\frac{F''(y)}{G} \frac{dG}{dw_*} = \left(1 + \frac{1}{F'}\right)^{-1} \left[\frac{F''}{(F')^2} - \frac{1}{2} F'' + \frac{1}{y} F' + \frac{2F'}{y} - \frac{2(y + \log 2)}{y}\right] \tag{103}
\]
where we have used $\log(-yF') = \log(2e^{-F'}) = \log 2 - F'$. From (100 on the page before) we get
\[
e^{w_*} \left(\frac{1}{w_*} - \frac{1}{w_*^2}\right) (-F''(y)) = \frac{1}{2} \tag{104}
\]
Using (104) in (103) we obtain, after some calculation,
\[
\frac{1}{G} \frac{dG}{dw_*} = \frac{1}{2} - \frac{1}{2w_*^2} - 2w_* - 2(y + \log 2). \tag{105}
\]
Solving (105) we see that (98 on the page before) is equivalent to (88 on page 60), noting that $\sqrt{y} = \sqrt{2/w_*} \exp(w_*/2)$. Of course, $G$ is determined only up to a multiplicative constant, which corresponds to $C_*/(2\sqrt{\pi})$ in (88 on page 60).
