Enumeration of derangements with descents in prescribed positions

Niklas Eriksen, Ragnar Freij and Johan Wästlund

Department of Mathematical Sciences, Chalmers University of Technology and University of Gothenburg, S-412 96 Göteborg, Sweden

We enumerate derangements with descents in prescribed positions. A generating function was given by Guo-Niu Han and Guoce Xin in 2007. We give a combinatorial proof of this result, and derive several explicit formulas. To this end, we consider fixed point λ-coloured permutations, which are easily enumerated. Several formulae regarding these numbers are given, as well as a generalisation of Euler’s difference tables. We also prove that except in a trivial special case, if a permutation π is chosen uniformly among all permutations on n elements, the events that π has descents in a set S of positions, and that π is a derangement, are positively correlated.

Keywords: Permutation statistic, fixed point, descent

1 Introduction

In a permutation π ∈ S_n, a descent is a position i such that π_i > π_{i+1}, and an ascent is a position where π_i < π_{i+1}. A fixed point is a position i where π_i = i. If π_i > i, then i is called an excedance, while if π_i < i, i is a deficiency. Richard Stanley conjectured that permutations in S_{2n} with descents at and only at odd positions (commonly known as alternating permutations) and n fixed points are equinumerous with permutations in S_n without fixed points, commonly known as derangements.

The conjecture was given a bijective proof by Chapman and Williams in 2007. The solution is quite straightforward: Assume π ∈ S_{2n} is alternating and F ⊆ [2n] is the set of fixed points, |F| ≤ n. Then removing the fixed points gives a permutation τ in S_{[2n]\setminus F} without fixed points, and π can be easily reconstructed from τ.

For instance, removing the fixed points in π = 326451 gives τ = 361 or τ = 231 if we reduce it to S_3. To recover π, we note that the fixed points in the first two descending blocks must be at the respective second positions, 2 and 4, since both τ_1 and τ_2 are excedances, that is above the fixed point diagonal τ_i = i. On the other hand, since τ_3 < 3, the fixed point in the third descending block comes in its first position, 5. With this information, we immediately recover π.

Alternating permutations are permutations which fall in and only in blocks of length two. A natural generalisation comes by considering permutations which fall in blocks of lengths...
a_1, a_2, \ldots, a_k and have k fixed points (this is obviously the maximum number of fixed points, since each descending block can have at most one). These permutations are in bijection with derangements which descend in blocks of length \( a_1 - 1, a_2 - 1, \ldots, a_k - 1 \), and possibly also between them, a fact which was proved by Guo-Niu Han and Guoce Xin (9).

In this article we compute the number of derangements which have descents in prescribed blocks and possibly also between them. A generating function was given by Han and Xin using a representation theory argument. We start by computing the generating function using simple combinatorial arguments (Section 3), and then proceed to extract a closed formula in Section 4.

Interestingly, this formula, which is a combination of factorials, can also be written as the same combination of an infinite family of other numbers, including the derangement numbers. We give a combinatorial interpretation of these families as the number of fixed point \( \lambda \)-coloured permutations.

For a uniformly chosen permutation, the events that it is a derangement and that its descent set is included in a given set are not independent. We prove that except for the permutations of odd length with no ascents, these events are positively correlated. In fact, we prove that the number of permutations which are derangements when sorted decreasingly in each block is larger when there are few and large blocks, compared to many small blocks. The precise statement is found in Section 7.

Finally, in Section 8 we generalise some results concerning Euler’s difference triangles from (10) to fixed point \( \lambda \)-coloured permutations, using a new combinatorial interpretation. This interpretation is in line with the rest of this article, counting permutations having an initial descending segment and \( \lambda \)-coloured fixed points to the right of the initial segment. In addition, we also derive a relation between difference triangles with different values of \( \lambda \).

There are many papers devoted to counting permutations with prescribed descent sets and fixed points, see for instance (6; 8) and references therein. More recent related papers include (4), where Corteel et al. considered the distribution of descents and major index over permutations without descents on the last \( i \) positions, and (2), where Chow considers the problem of enumerating the involutions with prescribed descent set.

This paper is an extended abstract, with some proofs missing. These can be found in the full paper (7).

## 2 Definitions and examples

Let \([i, j] = \{i, i+1, \ldots, j\}\) and \([n] = [1, n]\). We think of \([n]\) as being decomposed into blocks of lengths \( a_1, \ldots, a_k \), and we will consider permutations that decrease within these blocks. The permutations are allowed to decrease or increase in the breaks between the blocks.

Consider a sequence \( a = (a_1, a_2, \ldots, a_k) \) of nonnegative integers, with \( \sum_i a_i = n \), and let \( c_j = \sum_{i=1}^j a_i \). We denote by \( A_j \) the \( j \):th block of \( a \), that is the set \( A_j = [c_{j-1}+1, c_j] \subseteq [n] \). Throughout the paper, \( k \) will denote the number of blocks in a given composition. We let \( \mathcal{S}_a \subseteq \mathcal{S}_n \) be the set of permutations that have descents at every place within the blocks, and may or may not have descents in the positions \( c_j \). In particular we have \( \mathcal{S}_n = \mathcal{S}_{(1,1,\ldots,1)} \).

**Example 2.1** If \( n = 6 \) and \( a = (4,2) \), then we consider permutations that are decreasing in \([1,4]\) and in \([5,6]\). Such a permutation is uniquely determined by the partition of the numbers 1–6 into
these blocks, so the total number of such permutations is
\[
\binom{6}{4,2} = 15.
\]

Of these 15 permutations, those that are derangements are
\[
\begin{align*}
6543|21 \\
6542|31 \\
6541|32 \\
6521|43 \\
5421|63 \\
5321|64 \\
4321|65
\end{align*}
\]

We define \( D(a) \) to be the subset of \( S_a \) consisting of derangements, and our objective is to enumerate this set. For simplicity, we also define \( D_n = D(1, \ldots, 1) \).

For every composition \( a \) of \( n \), there is a natural map \( \Phi_a : S_n \to S_a \), given by simply sorting the entries in each block in decreasing order. For example, if \( \sigma = 25134 \), we have \( \Phi_{(3,2)}(\sigma) = 52143 \). Clearly each fiber of this map has \( a_1! \cdots a_k! \) elements.

The following maps on permutations will be used frequently in the paper.

**Definition 2.1** For \( \sigma \in S_n \), let \( \phi_{j,k}(\sigma) = \tau_1 \ldots \tau_{j-1}k\tau_j \ldots \tau_n \), where
\[
\tau_i = \begin{cases} 
\sigma_i & \text{if } \sigma_i < k \\
\sigma_i + 1 & \text{if } \sigma_i \geq k
\end{cases}
\]

Similarly, let \( \psi_j(\sigma) = \tau_1 \ldots \tau_{j-1}\tau_{j+1} \ldots \tau_n \) where
\[
\tau_i = \begin{cases}
\sigma_i & \text{if } \sigma_i < \sigma_j; \\
\sigma_i - 1 & \text{if } \sigma_i > \sigma_j.
\end{cases}
\]

Thus, \( \phi_{j,k} \) inserts the element \( k \) at position \( j \), increasing elements larger than \( k \) by one and shifting elements to the right of position \( j \) one step further to the right. The map \( \psi_j \) removes the element at position \( j \), decreasing larger elements by one and shifting those to its right one step left.

We will often use the map \( \phi_j = \phi_{j,j} \) which inserts a fixed point at position \( j \). The generalisations to a set \( F \) of fixed points to be inserted or removed are denoted \( \phi_F(\sigma) \) and \( \psi_F(\sigma) \), inserting elements in increasing order and removing them in decreasing order.

The maps \( \phi \) and \( \psi \) are perhaps most obvious in terms of permutation matrices. For a permutation \( \sigma \in S_n \), we get \( \phi_{j,k}(\sigma) \) by adding a new row below the \( k \)-th one, a new column before the \( j \)-th one, and an entry at their intersection. Similarly, \( \psi_j(\sigma) \) is obtained by deleting the \( j \)-th column and the \( \sigma_j \)-th row.
Example 2.2 We illustrate by showing some permutation matrices. For $\pi = 21$ and $F = \{1,3\}$, we get

\[
\begin{align*}
\pi & \quad \phi_{3,2}(\pi) & \quad \phi_F(\pi) & \quad \psi_4 \circ \phi_F(\pi)
\end{align*}
\]

where inserted points are labeled with an extra circle.

3 A generating function

Guo-Niu Han and Guoce Xin gave a generating function for $D(a)$ ([9], Theorem 9). In fact they proved this generating function for another set of permutations, equinumerous to $D(a)$ by ([9], Theorem 1). What they proved was the following:

**Theorem 3.1** The number $|D(a)|$ is the coefficient of $x_1^{a_1} \cdots x_k^{a_k}$ in the expansion of

\[
\frac{1}{(1 + x_1) \cdots (1 + x_k)(1 - x_1 - \cdots - x_k)}.
\]

The proof uses scalar products of symmetric functions. We give a more direct proof, with a combinatorial flavour. The proof uses the following definition, and the bijective result of Lemma 3.2.

**Definition 3.1** We denote by $D_j(a)$ the set of permutations in $S_a$ that have no fixed points in blocks $A_1, \ldots, A_j$. Thus, $D(a) = D_k(a)$.

Moreover, let $D^*_j(a)$ be the set of permutations in $S_a$ that have no fixed points in the first $j - 1$ blocks, but have a fixed point in $A_j$.

**Lemma 3.2** There is a bijection between $D_j(a_1, \ldots, a_k)$ and $D^*_j(a_1, \ldots, a_{j-1}, a_j + 1, a_{j+1}, \ldots, a_k)$.

**Proof:** Let $\sigma = \sigma_1 \cdots \sigma_n$ be a permutation in $D_j(a_1, \ldots, a_k)$, and consider the block $A_j = \{p, p+1, \ldots, q\}$. Then there is an index $r$ such that $\sigma_p \ldots \sigma_{r-1}$ are excedances, and $\sigma_r \ldots \sigma_q$ are deficiencies.

Now $\phi_r(\sigma)$ is a permutation of $[n + 1]$. It is easy to see that

$\phi_r(\sigma) \in S_{(a_1, \ldots, a_{j-1}, a_j + 1, a_{j+1}, \ldots, a_k)}$.

All the fixed points of $\sigma$ are shifted one step to the right, and one new is added in the $j$:th block, so

$\phi(\sigma) \in D^*_j(a_1, \ldots, a_{j-1}, a_j + 1, a_{j+1}, \ldots, a_k)$.

We see that $\psi_r(\phi_r(\sigma)) = \sigma$, so the map $\sigma \mapsto \phi_r(\sigma)$ is injective.

Similarly, for a permutation $\tau \in D^*_j(a_1, \ldots, a_{j-1}, a_j + 1, a_{j+1}, \ldots, a_k)$, let $r$ be the fixed point in $A_j$. Then $\psi_r(\tau) \in D_j(a_1, \ldots, a_k)$ and $\phi_r(\psi_r(\sigma)) = \sigma$. Thus, $\sigma \mapsto \phi_r(\sigma)$ is a bijection. \qed
We now obtain a generating function for $|D(a)|$, with a purely combinatorial proof. In fact, we even strengthen the result to give generating functions for $|D_j(a)|$, $j = 0, \ldots, k$. Theorem 3.1 then follows by letting $j = k$.

**Theorem 3.3** The number $|D_j(a)|$ is the coefficient of $x_1^{a_1} \cdots x_k^{a_k}$ in the expansion of

$$
\frac{1}{(1 + x_1) \cdots (1 + x_j)(1 - x_1 - \cdots - x_k)}.
$$

**Proof:** Let $F_j(x)$ be the generating function for $|D_j(a)|$, so that $|D_j(a_1, \ldots, a_k)|$ is the coefficient for $x_1^{a_1} \cdots x_k^{a_k}$ in $F_j(x)$. We want to show that $F_j(x)$ is given by (1).

By definition, $|D_0(a)| = |S_a|$. But a permutation in $S_a$ is uniquely determined by the set of $a_1$ numbers in the first block, the set of $a_2$ numbers in the second, etc. So $|D_0|$ is the multinomial coefficient $\left(\binom{n}{a_1, a_2, \ldots, a_k}\right)$. This is also the coefficient of $x_1^{a_1} \cdots x_k^{a_k}$ in the expansion of $1 + (\sum x_i)^n$. This holds also if $a_j = 0$, if the last term is interpreted as 0 in that case.

In terms of generating functions, this gives the recursion $F_{j-1}(x) = (1 + x_j)F_j(x)$. Hence $F_0(x) = F_j(x) \prod_{i \leq j}(1 + x_i)$. Thus,

$$
F_j(x) = \frac{F_0(x)}{(1 + x_1) \cdots (1 + x_j)} = \frac{1 + (\sum x_i)^2 + \cdots}{(1 + x_1) \cdots (1 + x_j)},
$$

and $|D_j(a)|$ is the coefficient for $x_1^{a_1} \cdots x_k^{a_k}$ in the expansion of $F_j$. □

**Proof of Theorem 3.1:** The set of derangements in $S_a$ is just $D(a) = D_k(a)$. Letting $j = k$ in Theorem 3.3 gives the generating function for $|D(a)|$. □

4 An explicit enumeration

It is not hard to explicitly calculate the numbers $|D(a)|$ from here. We will use $x^a$ as shorthand for $\prod_i x_i^{a_i}$.

Every term $x^a$ in the expansion of $F(x)$ is obtained by choosing $x_i^{b_i}$ from the factor $\frac{1}{1 + x_i} = \sum_{j \geq 0} (-x_i)^j$,
for some $0 \leq b_i \leq a_i$. This gives us a coefficient of $(-1)^{\sum b_j}$. For each choice of $b_1, \ldots, b_k$ we should multiply by $x^{a-b}$ from the factor

$$\frac{1}{(1 - x_1 - \cdots - x_k)} = 1 + \left( \sum x_i \right) + \left( \sum x_i \right)^2 + \cdots.$$  

But every occurrence of $x^{a-b}$ in this expression comes from the term $(\sum x_i)^{n-\sum b_j}$. Thus the coefficient of $x^{a-b}$ is the multinomial coefficient

$$\binom{n}{(a_1 - b_1, \ldots, a_k - b_k)} = \binom{n-\sum b_j}{a_1! \cdots (a_k - b_k)!}.  \tag{5}$$

Now since $|D(a)|$ is the coefficient of $x^a$ in $F_k(x)$, we conclude that

$$|D(a)| = \sum_{0 \leq b \leq a} (-1)^{\sum b_j} \frac{(n-\sum b_j)!}{(a_1 - b_1)! \cdots (a_k - b_k)!}.$$  

$$= \frac{1}{\prod a_i!} \sum_{0 \leq b \leq a} (-1)^{\sum b_j} \binom{n-\sum b_j}{a_1! \cdots (a_i - b_i)!} \prod_{i} \binom{a_i}{b_i} b_i!.  \tag{5}$$

While the last expression in Equation (5) seems a bit more involved than necessary, it turns out to generalise in a nice way.

5 Fixed point coloured permutations

A fixed point coloured permutation in $\lambda$ colours, or a fixed point $\lambda$-coloured permutation, is a permutation where we require each fixed point to take one of $\lambda$ colours. More formally it is a pair $(\pi, C)$ with $\pi \in S_n$ and $C : F_\pi \rightarrow [\lambda]$, where $F_\pi$ is the set of fixed points of $\pi$. When there can be no confusion, we denote the coloured permutation $(\pi, C)$ by $\pi$. Thus, fixed point 1-coloured permutations are simply ordinary permutations and fixed point 0-coloured permutations are derangements. The set of fixed point $\lambda$-coloured permutations on $n$ elements is denoted $S_\lambda^\lambda$.

For the number of $\lambda$-fixed point coloured permutations on $n$ elements, we use the notation $|S_\lambda^\lambda| = f_\lambda(n)$, the $\lambda$-factorial of $n$. Of course, we have $f_0(n) = D_n$ and $f_1(n) = n!$. Clearly,

$$f_\lambda(n) = \sum_{\pi \in S_n} \lambda^{\text{fix}(\pi)},$$

where fix($\pi$) is the number of fixed points in $\pi$, and we use this formula as the definition of $f_\lambda(n)$ for $\lambda \notin \mathbb{N}$.

Lemma 5.1 For $\nu, \lambda \in \mathbb{C}$ and $n \in \mathbb{N}$, we have

$$f_\nu(n) = \sum_{j} \binom{n}{j} f_\lambda(n-j) \cdot (\nu - \lambda)^j.$$
Proof: It suffices to show this for \(\nu, \lambda, n \in \mathbb{N}\), since the identity is polynomial in \(\nu\) and \(\lambda\), so if it holds on \(\mathbb{N} \times \mathbb{N}\) it must hold on all of \(\mathbb{C} \times \mathbb{C}\).

We divide the proof into three parts. First, assume \(\nu = \lambda\). Then all terms in the sum vanish except for \(j = 0\), when we get \(f_\nu(n) = f_\lambda(n)\).

Secondly, assuming \(\nu > \lambda\), we let \(j\) denote the number of fixed points in \(\pi \in S_\nu^n\) which are coloured with colours from \([\lambda + 1, \nu]\). These fixed points can be chosen in \(\binom{n}{j}\) ways, there are \(f_\lambda(n-j)\) ways to permute and colour the remaining elements, and the colours of the high coloured fixed points can be chosen in \(\binom{\nu - \lambda}{j}\) ways. Thus, the equality holds.

Finally, assuming \(\nu < \lambda\), we prescribe \(j\) fixed points in \(\pi \in S_\lambda^n\) which only get to choose their colours from \([\nu + 1, \lambda]\). These fixed points can be chosen in \(\binom{n}{j}\) ways, the remaining elements can be permuted in \(f_\lambda(n-j)\) ways and the chosen fixed points can be coloured in \(\binom{\lambda - \nu}{j}\) ways, so by the principle of inclusion-exclusion, the equality holds.

With \(\lambda = 1\) and replacing \(\nu\) by \(\lambda\), we find that

\[
f_\lambda(n) = n! \left( 1 + \frac{(\lambda - 1)}{1!} + \frac{(\lambda - 1)^2}{2!} + \cdots + \frac{(\lambda - 1)^n}{n!} \right) = n! \exp_n(\lambda - 1). \quad (6)
\]

Here we use \(\exp_n\) to denote the truncated series expansion of the exponential function. In fact, \(\lim_{n \to \infty} n! e^{(\lambda - 1)} - f_\lambda(n) = 0\) for all \(\lambda \in [-1, 1]\), although we cannot in general approximate \(f_\lambda(n)\) by the nearest integer of \(n!e^{\lambda - 1}\) as for derangements.

The formula \((6)\) also shows that

\[
f_\lambda(n) = nf_\lambda(n-1) + (\lambda - 1)^n, \quad f_\lambda(0) = 1 \quad (7)
\]

which generalises the well known recursions \(|D_n| = n|D_{n-1}| + (-1)^n\) and \(n! = n(n-1)!\).

6 Enumerating \(D(a)\) using fixed point coloured permutations

Another consequence of Equation \((6)\) is that the \(\lambda\)-factorial satisfies the following rule for differentiation, which is similar to the rule for differentiating powers of \(\lambda\):

\[
\frac{d}{d\lambda} f_\lambda(n) = n \cdot f_\lambda(n-1). \quad (8)
\]

Regarding \(n\) as the cardinality of a set \(X\), the differentiation rule \((8)\) translates to

\[
\frac{d}{d\lambda} f_\lambda(|X|) = \sum_{x \in X} f_\lambda(|X \setminus \{x\}|). \quad (9)
\]

Products of \(\lambda\)-factorials can of course be differentiated by the product formula. This implies that if \(X_1, \ldots, X_k\) are disjoint sets, then

\[
\frac{d}{d\lambda} \prod_i f_\lambda(|X_i|) = \sum_{x \in \bigcup_i X_j} \prod_i f_\lambda(|X_i \setminus \{x\}|).
\]
Now consider the expression
\[ \sum_{B \subseteq [n]} (-1)^{|B|} f_\lambda ([n] \setminus B) \prod_{i} f_\lambda (|A_i \cap B|). \] (10)

This is obtained from the right-hand side of Equation (5) by deleting the factor $1/\prod a_i!$ and replacing the other factorials by $\lambda$-factorials. For $\lambda = 1$, the expression (10) is therefore $|\Phi^{-1}_a(D(a))|$, the number of permutations that, when sorted in decreasing order within the blocks, have no fixed points. We want to show that (10) is independent of $\lambda$. The derivative of (10) is, by the rule (9) of differentiation,
\[ \sum_{B \subseteq [n]} (-1)^{|B|} \sum_{x=1}^{n} f_\lambda ([n] \setminus B \setminus \{x\}) \prod_{i} f_\lambda (|(A_i \cap B) \setminus \{x\}|). \] (11)

Here each product of $\lambda$-factorials occurs once with $x \in B$ and once with $x \notin B$. Because of the sign $(-1)^{|B|}$, these terms cancel. Therefore (11) is identically zero, which means that (10) is independent of $\lambda$. Hence we have proven the following theorem:

**Theorem 6.1** For any $\lambda \in \mathbb{C}$, the identity
\[ |\Phi^{-1}_a(D(a))| = \sum_{0 \leq b \leq a} (-1)^{\sum b_j} \cdot f_\lambda \left(n - \sum b_j \right) \prod_{i} \left(\frac{a_i}{b_i} \right) \cdot f_\lambda (b_i) \] (12)
holds.

A particularly interesting special case is when we put $\lambda = 0$. In this case, $f_0(n) = D_n$, so
\[ |D(a)| = \frac{1}{\prod a_i!} \sum_{0 \leq b \leq a} (-1)^{\sum b_j} D_{n - \sum b_j} \prod_{i} \left(\frac{a_i}{b_i} \right) D_{b_i}. \] (13)

This equation has some advantages over Equation (5). It has a clear main term, the one with $b = 0$. Moreover, since $D_1 = 0$, the number of terms does not increase if blocks of length 1 are added.

It should be pointed out that Theorem 6.1 can be proven directly for all $\lambda$ in a recursive manner, using neither the differentiation rule 8, nor the generating function in Theorem 3.3. This alternative proof is rather lengthy, and can be found in (7).

We also note that Theorem 6.1 can be used to enumerate permutations in $\mathcal{S}_a$ with $\mu$ allowed fixed point colours, and even $\mu_i$ fixed point colours in block $A_i$.

**Corollary 6.2** For any $\lambda \in \mathbb{C}$ and natural numbers $\mu_i, 1 \leq i \leq k$, the number of permutations $(\pi, C)$ where $\pi \in \mathcal{S}_a$ and $(j \in A_i, \pi(j) = j) \Rightarrow C(j) = [\mu_i]$ is given by
\[ \sum_{0 \leq c \leq 1} \sum_{0 \leq b \leq a-c} (-1)^{\sum b_j} f_\lambda \left(\sum a_j - \sum c_j - \sum b_j \right) \prod_{i} \left(\frac{a_i - c_i}{b_i} \right) f_\lambda(b_i) \cdot \mu_i^{c_i}. \]
Enumeration of derangements with descents in prescribed positions

393

Proof: The numbers \(c_i\) are one if \(A_i\) contains a fixed point and zero otherwise. We may remove these fixed points and consider a fixed point free permutation, enumerated above. We then reinsert the fixed points and colour them in every allowed combination. \(\square\)

7 A correlation result

Taking a permutation at uniformly random in \(\mathfrak{S}_n\), the chances are about \(1/e\) that it is a derangement, since there are \(n!\exp(-1)\) derangements in \(\mathfrak{S}_n\). Moreover, there are \(n!/a!\) permutations in \(\mathfrak{S}_a\).

If belonging to \(\mathfrak{S}_a\) and being fixed point free were two independent events, we would have \(n!/a!\) permutations in \(\Phi^{-1}(D(a))\). This is not the case, although the main term in Equation 13 is this very number. The special case \(b = (1, 1, \ldots, 1)\) of Theorem 7.1 says, that belonging to \(\mathfrak{S}_a\) and being a derangement are almost always positively correlated events. The sole exception is when \(a\) is a single block of odd length, in which case every permutation gets a fixed point when sorted.

For two compositions \(a\) and \(b\) of \(n\), we say that \(a \geq b\) if, when sorted decreasingly, \(\sum_{i \leq j} a_i \geq \sum_{i \leq j} b_i\) for all \(j\). Then we get the following monotonicity theorem.

Theorem 7.1 If \(a \geq b\) and \(a\) is not a single block of odd size, then

\[|\Phi^{-1}_a(D(a))| \geq |\Phi^{-1}_b(D(b))|\]

The theorem follows from a series of lemmata, all included in (7). The main point is proving that shifting any position from a smaller block to a larger one almost never decreases the number \(|\Phi^{-1}_a(D(a))|\). Equivalently, for fixed \(a_3, \ldots, a_k\), and \(a = a_1 + a_2\) fixed, the function \(|\Phi^{-1}_a(D(a))|\) is unimodal in \(a_1\) (with the trivial exception).

A weaker, but perhaps more natural version of the correlation result is the following.

Corollary 7.2 Let \(n \geq 2\) and let \(\pi \in \mathfrak{S}_n\) be chosen uniformly at random. Then the number of descents in \(\pi\) is positively correlated with the event that \(\pi\) is a derangement.

Proof: For any \(i\) let \(\chi_i\) be the indicator variable of the event that \(i\) is a descent of \(\pi\). Let \(\text{Der}(\pi)\) be the event that \(\pi\) is a derangement. With \(a = (1, 1, \ldots, 1)\) and \(b = (1, 1, \ldots, 1)\) in Theorem 7.1, we see that each \(\chi_i\) is positively correlated with \(\text{Der}(\pi)\).

The number of descents in \(\pi\) is just \(\sum \chi_i\), and thus also has positive correlation with \(\text{Der}(\pi)\). \(\square\)

8 Euler’s difference tables fixed point coloured

Leonard Euler introduced the integer table \((\xi_k^n)_{0 \leq k \leq n}\) by defining \(\xi^n_n = n!\) and \(\xi^{k-1}_n = \xi^k_n - \xi^{k-1}_n\) for \(1 \leq k \leq n\). Apparently, he never gave a combinatorial interpretation, but a simple one was given by Dumont and Randrianarivony in (5). Indeed, \(\xi^k_n\) gives the number of permutations \(\pi \in \mathfrak{S}_n\) such that there are no fixed points on the last \(n - k\) positions. Thus, \(\xi^0_n = D_n\). A \(q\)-analogue of the same result was given in (3).
It is clear from the recurrence that \( k! \) divides \( e_n^k \). Thus, we can define the integers \( d_n^k = e_n^k/k! \). These have recently been studied by Fanja Rakotondrajao [10], and the combinatorial interpretation of \( d_n^k \) given there was that they count the number of permutations \( \pi \in \mathfrak{S}_n \) such that there are no fixed points on the last \( n-k \) positions and such that the first \( k \) elements are all in different cycles.

We will now generalise these integer tables to any number \( \lambda \) of fixed point colours, and give a combinatorial interpretation that is more in line with the context of this article. The relations in [10] generalise nicely to the case with general \( \lambda \).

Let \( e_n^k(\lambda) \) be defined by \( e_n^k(\lambda) = n! \) and \( e_n^{k-1}(\lambda) = e_n^k(\lambda) + (\lambda - 1)e_n^{k-1}(\lambda) \). Then, a natural combinatorial interpretation for non-negative integer \( \lambda \) is that \( e_n^k(\lambda) \) count the number of permutations \( \pi \in \mathfrak{S}_n \) such that fixed points on the last \( n-k \) positions may be coloured in any one of \( \lambda \) colours.

Similarly, we can define \( d_n^k(\lambda) = e_n^k(\lambda)/k! \) and interpret these numbers as counting the number of permutations \( \pi \in \mathfrak{S}_{(k,1,1,...,1)} \subseteq \mathfrak{S}_n \) such that fixed points on the last \( n-k \) positions may be coloured in any one of \( \lambda \) colours. The set of these permutations is denoted \( D_n^k(\lambda) \). Thus, our interpretation for \( \lambda = 0 \) states that apart from forbidding fixed points at the end, we also demand that the first \( k \) elements are in descending order. Equivalently, we could have considered permutations ending with \( k-1 \) ascents and having \( \lambda \) fixed point colours in the first \( n-k \) positions, to be closer to the setting in [10].

There are a couple of relations that can proven bijectively with this interpretation, generalising the results with \( \lambda = 0 \) from [10]. The following propositions are all given bijective proofs in [7].

**Proposition 8.1** For integers \( 1 \leq k \leq n \) and \( \lambda \in \mathbb{C} \) we have

\[
d_n^{k-1}(\lambda) = kd_n^k(\lambda) + (\lambda - 1)d_n^{k-1}(\lambda).
\]

**Proposition 8.2** For integers \( 0 \leq k \leq n-1 \) and \( \lambda \in \mathbb{C} \) we have

\[
d_n^k(\lambda) = nd_n^{k-1}(\lambda) + (\lambda - 1)d_n^{k-1}(\lambda).
\]

**Proposition 8.3** For integers \( 0 \leq k \leq n-1 \) and \( \lambda \in \mathbb{C} \) we have

\[
d_n^k(\lambda) = (n + (\lambda - 1))d_{n-1}^k(\lambda) - (\lambda - 1)(n - k - 1)d_{n-2}^k(\lambda).
\]

These formulae allow us to once again deduce the recursion for the \( \lambda \)-factorials. Using Proposition 8.3 extended to \( k = -1 \) and \( d_{n-1}^{-1}(\lambda) = 1 \), we get by induction \( d_{n-1}^{-1} = (\lambda - 1)d_{n-1}^{-1} \) and hence \( d_n^{-1} = (\lambda - 1)^{n+1} \). Thus, by Proposition 8.2 we have \( f_\lambda(n) = d_n^0 = nd_{n-1}^0 + (\lambda - 1)^n \). We can also use Proposition 8.3 to obtain, using (7) and \( f_\lambda(n) = d_n^0 \), that

\[
f_\lambda(n) = (n + \lambda - 1)f_\lambda(n-1) - (\lambda - 1)(n-1)f_\lambda(n-2) = (n-1)(f_\lambda(n-1) + f_\lambda(n-2)) + \lambda(f_\lambda(n-1) - (n-1)f_\lambda(n-2)) = (n-1)(f_\lambda(n-1) + f_\lambda(n-2)) + \lambda(\lambda - 1)^{n-1},
\]

which specialises to the well-known

\[
D_n = (n-1)(D_{n-1} + D_{n-2})
\]
and \( n! = (n - 1)((n - 1)! + (n - 2)!). \)

We close this section by noting that Lemma 5.1 can be generalised to \( d_n^k(\lambda) \) as follows. The proof is completely analogous.

**Proposition 8.4** For \( \nu, \lambda \in \mathbb{C} \) and \( 0 \leq k \leq n \in \mathbb{N} \), we have

\[
d_n^k(\nu) = \sum_j \binom{n-k}{j} d_{n-j}^k(\lambda)(\nu - \lambda)^j.
\]

9 **Open problems**

While many of our results have been shown bijectively, there are a few that still seek their combinatorial explanation. The most obvious are these.

**Problem 9.1** Give a combinatorial proof, using the principle of inclusion-exclusion, of Theorem 6.1.

**Problem 9.2** Give a bijection \( f : \mathfrak{S}_n \to \mathfrak{S}_n \) such that \( \pi \in D(a_1, a_2, \ldots, a_k) \Rightarrow f(\pi) \in D(a_1 + 1, a_2 - 1, a_3, \ldots, a_k) \) whenever \( a_1 \geq a_2 \) and \( a \neq (2m, 1) \).

We would also like the rearrangement of blocks in \( D(\alpha) \) to get a simple description.

**Problem 9.3** For any \((a_1, \ldots, a_k)\) and any \( \sigma \in \mathfrak{S}_k \), give a simple bijection \( f : D(a_1, \ldots, a_k) \to D(a_{\sigma_1}, \ldots, a_{\sigma_k}) \).

Instead of specifying descents, we could specify spots where the permutation must not descend. This would add some new features to the problem, as ascending blocks can contain several fixed points, whereas descending blocks can only contain one.

**Problem 9.4** Given a composition \( \alpha \), find the number of derangements that ascend within the blocks.
