The Ackermann function is a fascinating and well studied paradigm for a function which eventually dominates all primitive recursive functions. By a classical result from the theory of recursive functions it is known that the Ackermann function can be defined by an unnested or descent recursion along the segment of ordinals below $\omega^\omega$ (or equivalently along the order type of the polynomials under eventual domination). In this article we give a fine structure analysis of such a Ackermann type descent recursion in the case that the ordinals below $\omega^\omega$ are represented via a Hardy Ramanujan style coding. This paper combines number-theoretic results by Hardy and Ramanujan, Karamata’s celebrated Tauberian theorem and techniques from the theory of computability in a perhaps surprising way.

Keywords: Ackermann function, Tauberian theorem

1 Introduction

This article is part of a general investigation on the relationships between enumerative combinatorics and the theory of computability. (See, for example, Weiermann (2003, 2004) for further related material on this topic.)

In this paper we focus on classifying a Friedman-style recursion schema for the Ackermann function using "asymptotic formulæ for the distribution of integers of various types" in the spirit of Hardy and Ramanujan (1916).

The Ackermann function emerges naturally from a given base function, like the successor function by iterated iteration and a final diagonalization. For example, let $F_0(n) := n + 1$ and $F_{k+1}(n) := F_k(n + 1) \ldots$ (n + 1 times).

Then $A(n) := F_n(n)$ is a typical version of the Ackermann function. A common feature of these definitions of such a function is that the resulting function $A$ eventually dominates every function $F_k$ and hence $A$ is not primitive recursive (since every primitive recursive function can be computed with time bound $F_k$ for some $k$). We consider all such functions as equivalent and call them Ackermannian for the rest of the paper.

Ackermannian functions grow very rapidly, since for example $F_3$ grows like the superexponential function. Therefore they usually do not show up in mathematical textbooks on analytic number theory. The deeper reason for this can be described briefly as follows. Usual analytic number theory can be formalized within a logical framework RCA$_0$ (see, for example, Simpson (1985) for a definition) which has only primitive recursive functions as provably total recursive functions by a standard result in foundations. Thus Ackermannian functions are beyond the scope of analytic number theory.

Nevertheless this observation does not exclude that one can study the behaviour of Ackermannian functions using results from analytic number theory and this will be carried out in this paper.

The link between $A$ and the mathematics from the Hardy Ramanujan paper about asymptotic formulae is provided by the (codes for) ordinals below $\omega^\omega$. Motivated by their study of highly composite numbers Hardy and Ramanujan were interested in the asymptotic behaviour of products of the form $p_1^{a_1} \cdots p_n^{a_n}$ where $a_1 \geq \ldots \geq a_n$ and $p_i$ denotes the $i$-th prime. From the logical viewpoint it is very natural to consider such products as codes for ordinals below $\omega^\omega$. Simply associate to $p_1^{a_1} \cdots p_n^{a_n}$ the ordinal $\omega^{a_1 - 1} + \ldots + \omega^{a_n - 1}$ and vice versa.

To ordinals below $\omega^\omega$ we may associate by recursion a hierarchy of number-theoretic functions as follows. Let $H_0(n) := n$, $H_{\alpha+1}(n) := H_{\alpha}(n+1)$ and $H_\lambda(n) := H_{\lambda_{|\alpha}}(n)$ where $\lambda$ is a limit ordinal of the form $\lambda = \omega^{a_1} + \ldots + \omega^{a_m}$ where $a_1 \geq \ldots \geq a_m \geq 1$ and $\lambda[n] = \omega^{a_1} + \ldots + \omega^{a_m} - 1 \cdot (n + 1)$ is the $n$-th member of the canonical fundamental sequence which converges to $\lambda$. A small calculation shows $A(n) = H_{\omega^\alpha}(n)$ for every natural number $n$. Since $\omega^\omega$ is the $n$-th member of the canonical fundamental sequence which converges to $\omega^\omega$ we obtain $A(n) = H_{\omega^\omega}(n)$ in accordance to the definition above. Thus $A$ can be defined by an unnested recursion along $\omega^\alpha$. (This result is a special case of a more general result by Tait about the relationship between nested and unnested recursion.)

In this paper we investigate the fine structure of related recursions which lead to functions of similar growth as $A$. In particular we focus on a Friedman-style description of $A$ via a descent recursion Friedman and Sheard (1995); Simpson (1985); Smith (1985).

For describing this in some more detail we need some further terminology. Let HR be the set of numbers considered by Hardy and Ramanujan. For $a, b \in HR$ let $a \prec b$ if the ordinal associated to $a$ is less than the ordinal associated to $b$. For a given binary number-theoretic function $f$ let $F_f$ be defined as follows. $F_f(n) := \max \{ K : (\exists m_1, \ldots, m_K \in HR)[m_1 > \ldots > m_K \& (\forall i \in \{1, \ldots, K\})m_i \leq f(n,i)] \}$.

Functions like $F_f$ occur naturally in proof-theoretic investigations about provably recursive functions of formal proof systems for arithmetic Friedman and Sheard (1995). Moreover they can be used as scales for comparing hierarchies of number theoretic functions Buchholz et al. (1994). For example, the Ackermannian functions can be described in terms of suitable $F_f$ as follows.

Let $2_0(i) := i$ and $2_{K+1}(i) := 2^{2^i}$ and let $f_K(n, i) := 2_K(n + i)$. Then according to a theorem of Friedman and Sheard (1995) there is a $K$ such that $A$ and $F_{f_K}$ have the same growth rate in the sense that there are elementary functions (primitive recursive functions which are bounded by a fixed number of iterates of the exponential function) $p$ and $q$ such that $A(n) \leq F_{f_K}(p(n))$ and $F_{f_K}(n) \leq A(q(n))$.

It seems quite natural to ask whether it is possible to classify those functions $f$ for which the induced function $F_f$ has the same growth rate as $A$. Our main theorem runs as follows. For $\alpha \prec \omega^\omega$ let $g_\alpha(n, i) := n + 2^{H^{-1}_\alpha(i)} \cdot 7$ where $H^{-1}_\alpha(i) = \min \{ k : H_{\alpha}(k) \geq i \}$. (These functions grow very slowly for large $\alpha$ since $H_\alpha$ grows then rather fastly.) Then $F_{g_\alpha}$ is primitive recursive iff $\alpha \prec \omega^\omega$. Moreover $F_{g_\omega^\omega}$ and $A$ have the same growth rate in the sense as indicated above.

These purely foundational investigations led us naturally to questions about the asymptotic behaviour
of the number of products of the form \( p_1^{a_1} \cdots p_n^{a_n} \leq x \) where \( d \geq a_1 \geq \ldots \geq a_n \) and \( d \) is a fixed natural number. Such bounds are in the spirit of the Hardy Ramanujan style Tauberian theorem. However they can be obtained by the celebrated Tauberian theorem of Karamata. The result which is then obtained in this paper is that

\[
\# \{ p_1^{a_1} \cdots p_n^{a_n} \leq x : d \geq a_1 \geq \ldots \geq a_n \geq 1 \} \sim \frac{1}{(d!)^2} \left( \frac{\ln(x)}{\ln(\ln(x))} \right)^d \text{ as } x \to \infty.
\]

We believe that these number-theoretic investigations have their interest and beauty in their own and we plan to push these further. Moreover we supply these number-theoretic results with a natural application in the theory of recursive functions and we hope that number-theorists as well as logicians may find this relationship between number theory and logic attractive.

2 The number-theoretic part

This section of the paper deals with purely number-theoretic problems about the asymptotics of Hardy Ramanujan numbers. It can be read independently from the following section which provides the applications to Ackermannian functions.

As indicated before, let \( p_i \) denote the \( i \)-th prime number. Let

\[
\text{HR} = \{ p_1^{a_1} \cdots p_n^{a_n} : a_1 \geq \ldots \geq a_n \geq 1 \}
\]

be the set of integers which has been investigated by Hardy and Ramanujan. For \( a,b \in \text{HR} \) let \( a \prec b \) be defined as follows. Assume \( a = p_1^{a_1} \cdots p_m^{a_m} \) and \( b = p_1^{b_1} \cdots p_n^{b_n} \). Then \( a \prec b \) iff either \( m < n \) and \( a_i = b_i \) for \( 1 \leq i \leq m \) or there is an \( i \leq \min\{m,n\} \) such that \( a_i < b_i \) and \( a_j = b_j \) for \( 1 \leq j < i \). This ordering is quite natural since it is the order type of the polynomials under eventual domination. Indeed, for \( a = p_1^{a_1} \cdots p_m^{a_m} \in \text{HR} \) let \( f_a(x) = x^{a_1} + \cdots + x^{a_m} \). Then \( a \prec b \) iff \( f_a \) is eventually dominated by \( f_b \).

Readers familiar with ordinals will recognize that the order type of \( \prec \) is \( \omega^\omega \).

Let

\[
hr(x) := \#\{ a \in \text{HR} : a \leq x \}
\]

and let

\[
hr_d(x) := \#\{ a \in \text{HR} : a \leq x & a \prec p_1^{d+1} \}.
\]

In their paper Hardy and Ramanujan showed the following beautiful result.

**Theorem 1 (Hardy and Ramanujan [1916])**

\[
\ln(hr(x)) \sim \frac{2}{\sqrt{3}} \pi \sqrt{\frac{\ln(x)}{\ln(\ln(x))}} \text{ as } x \to \infty.
\]

In this section we are going to show that \( hr_d(x) \sim \frac{1}{(d!)^2} \left( \frac{\ln(x)}{\ln(\ln(x))} \right)^d \text{ as } x \to \infty \) and we draw an easy corollary that is needed in the desired application.

Following Hardy and Ramanujan it is convenient to define \( l_n := p_1 \cdots p_n \). Let \( L_e(x) := \#\{ l_1 \cdots l_e \leq x : 1 \leq i_1 \leq \ldots \leq i_e \} \).

**Lemma 1** \( hr_d(x) = \sum_{e=1}^{d} L_e(x) \).
Proof. It suffices to show
\[ \{ a \in HR : a \leq x \ & a < p_1^{d+1} \} = \bigcup_{e=1}^{d} \{ l_{i_1} \cdots l_{i_e} \leq x : 1 \leq i_1 \leq \ldots \leq i_e \}. \]

This is more or less obvious by grouping the factors appropriately together. (In some sense this is similar when one counts partitions and their conjugates. In terms of block diagrams this simply means that we are counting blocks at one time via columns and at the other time via rows.) Nevertheless we give some more formal details for the reader's convenience.

"\( \subseteq \)". Assume \( a \in HR, a \leq x \) and \( a < p_1^{d+1} \). Then \( a = p_1^{a_1} \cdots p_n^{a_n} \) where \( d \geq a_1 \geq \ldots \geq a_n \geq 1 \). Choose \( i_1 < \ldots < i_r \) for some \( r \leq d \) such that \( a_1 = \ldots = a_{i_1} > a_{i_1+1} = \ldots = a_{i_2} > a_{i_2+1} = \ldots = a_{i_r} > a_{i_r+1} = \ldots = a_n \). Then \( a = l_1^{a_{i_1} - a_{i_1} + 1} l_2^{a_{i_1} + a_{i_2} + 1} \cdots l_r^{a_{i_r}} \) and the number of factors is equal to \( a_1 + \ldots + a_r \leq e \) and \( a_j \geq 1 \). Then \( l = (p_1 \cdots p_{i_1})^{a_{i_1} + \ldots + a_{i_r}} \cdot (p_{i_1+1} \cdots p_{i_2})^{a_{i_2} + \ldots + a_{i_r}} \cdots (p_{i_r+1} \cdots p_n)^{a_n} < p_1^{d+1} \). \( \square \)

Let \( L(s) := \sum_{n=1}^{\infty} l_n^{-s} \).

**Theorem 2 (Hardy and Ramanujan (1916))** \( L(s) \sim \frac{1}{s \ln(s)} \) as \( s \to 0^+ \).

Let \( M_d(s) = \sum_{i_1 \geq \ldots \geq i_d \geq 1} (l_{i_1} \cdots l_{i_d})^{-s} \).

**Lemma 2** \( M_d(s) \sim \frac{1}{d! \left( \frac{1}{s \ln(s)} \right)^d} \) as \( s \to 0^+ \).

Proof. By induction on \( d \). For \( d = 1 \) the claim is Theorem 2. Let

\[ \tilde{L}(s) = \sum_{i_1 \geq 1} l_1^{-s} \sum_{i_2 \geq \ldots \geq i_d \geq 1} (l_{i_2} \cdots l_{i_d})^{-s}. \]

The induction hypothesis and Theorem 2 yield \( \tilde{L}(s) \sim \frac{1}{s \ln(s)} \left( \frac{1}{\ln(s)} \right)^d \sim \frac{1}{s \ln(s)} \) as \( s \to 0^+ \). We have for \( s > 0 \)

\[ \tilde{L}(s) = \sum_{i_1 \geq i_2 \geq \ldots \geq i_d \geq 1} (l_{i_1} \cdots l_{i_d})^{-s} + \sum_{i_2 \geq i_3 \geq \ldots \geq i_d \geq 1} (l_{i_2} \cdots l_{i_d})^{-s} + \ldots + \sum_{i_d \geq \ldots \geq i_d \geq 1} (l_{i_d})^{-s} - \sum_{i_d \geq \ldots \geq i_d \geq 1} (l_{i_d})^{-s} - \ldots - \sum_{i_d \geq \ldots \geq i_d \geq 1} (l_{i_d})^{-s} = d \cdot M_d(s) - R_2(s) - \ldots - R_d(s). \]
where \( R_k(s) = \sum_{i_2 \geq \ldots \geq i_d \geq 1} (l_1 \cdot \ldots \cdot l_d)^{-i} \) for \( 2 \leq k \leq d \). For positive \( s \) we have \( R_k(s) \leq \sum_{i_2, i_3, \ldots, i_d = 1} (l_1 \cdot \ldots \cdot l_d)^{-i} = L(s)^{d-2} \cdot L(2s) \). Thus \( R_k(s) = o(L(s)) \) as \( s \to 0^+ \) and the result follows.

A function \( f : \mathbb{R} \to [0, \infty] \) is called slowly varying if

\[
\lim_{t \to \infty} \frac{f(tx)}{f(t)} = 1
\]

for \( x > 0 \).

**Theorem 3 (Karamata’s Tauberian Theorem, Bingham et al. (1987))** Let \( U \) be a non decreasing right continuous function on the real numbers with \( U(x) = 0 \) for all \( x < 0 \). Let \( LU(s) = \int_0^\infty \exp(-sx) dU(x) \). If \( f : \mathbb{R} \to [0, \infty] \) varies slowly and \( c \geq 0 \), \( p \geq 0 \) the following are equivalent:

1. \( U(x) \sim \frac{c \rho f(x)}{\Gamma(1+p)} \) as \( x \to \infty \).
2. \( LU(s) \sim cs^{-p}f(\frac{1}{2}) \) as \( s \to 0^+ \).

As a nice application we obtain the following result.

**Theorem 4** \( hr_d(x) \sim \frac{1}{(d!)^x} \left( \frac{\ln(x)}{\ln(n)} \right)^d \) as \( x \to \infty \).

**Proof.** Define natural numbers \( a_n \) by the equation

\[
\sum_{n=1}^\infty a_n n^{-s} = \sum_{e=1}^d M_e(s).
\]

Then \( \sum_{n \leq x} a_n = hr_d(x) \). Let \( U(x) = \sum_{\ln(n) \leq x} a_n \). Then, as \( s \to 0^+ \),

\[
LU(s) = \int_0^\infty \exp(-sx) dU(x) = \sum_{n=1}^\infty a_n n^{-s} \sim \sum_{e=1}^d \frac{1}{e!} \left( \frac{1}{s\ln(\frac{1}{2})} \right)^e \sim \frac{1}{d!} \left( \frac{1}{s\ln(\frac{1}{2})} \right)^d.
\]

The function \( s \mapsto \frac{1}{(\ln(x))^d} \) is slowly varying. Theorem 3 yields \( U(x) \sim \frac{1}{(d!)^x} \left( \frac{x}{\ln(n)} \right)^d \) as \( x \to \infty \). Now \( \sum_{n \leq x} a_n = U(\ln(x)) \) and the result follows.

With \( |i| \) we denote the binary length of \( i \) which is the number of digits when we write \( i \) with respect to base 2. Moreover let \( |x| \) be the least integer less than or equal to \( x \). The following corollary is needed in the desired applications in the next section. Informally speaking it says that the major part of the number of prime number products under consideration is not seriously diminished when square root of log sized initial parts are not taken into account.

**Corollary 1** Let \( k : \mathbb{N}^2 \to \mathbb{N} \) such that \( k(n, i) \leq n + 1 + |\sqrt{|i|}| \) for all \( n, i \). Then for each natural number \( n \) there is a constant \( K(n) \) such that

\[
\#\{ a \in \mathbb{N} : a \leq 2^{n+1 + \sqrt{|i|}} \text{ and } a = p_{k(n,i)+1}^{a_{k(n,i)+1}} \cdots p_{e}^{a_e} \text{ for } n+3 > a_{k(n,i)+1} \geq \cdots \geq a_r \geq 1 \} \geq 2^{|i|}
\]

for \( i \geq K(n) \).
Proof. Let

\[ X(n, i) = \{ a \in \text{HR} : a < p_1^{i+3} & a \leq 2^{n+1/2^{n(i)}} \}, \]

\[ Y(n, i) = \{ a \in \text{HR} : a < p_1^{i+3} & a = p_1^{a_1} \cdots p_q^{a_q} : q \leq k(n, i) \}, \]

\[ Z(n, i) = \{ a \in \mathbb{N} : a \leq 2^{n+1/2^{n(i)}} & a = p_1^{a_1(n,i)+1} \cdots p_r^{a_r} \]

\& \ n+3 > a_{k(n,i)+1} \geq \cdots \geq a_r \geq 1 \} .

Theorem 4 yields the existence of a constants \( K_1(n), K_2(n) \) such that

\[ \#X(n, i) \geq K_2(n) \, (2^{|i|})^{\frac{n+2}{3}} \cdot |i|^{-n-2} \quad (1) \]

for \( i \geq K_1(n) \).

By the standard bounds on the number of ordered sequences of a fixed lengths (where repetitions are allowed) we obtain

\[ \#Y(n, i) \leq \sum_{r \leq k(n,i)} (n+3)^r \leq (n+3)^{k(n,i)+1} . \]

Every product \( a = p_1^{a_1} \cdots p_r^{a_r} \in X(n, i) \) yields by splitting up a unique product \( p_1^{a_1} \cdots p_{k(n,i)}^{a_{k(n,i)}} \in Y(n, i) \) and an empty product if \( r \leq k(n,i) \) and a unique product \( p_1^{a_1} \cdots p_{k(n,i)}^{a_{k(n,i)}} \in Y(n, i) \) and a unique \( p_{k(n,i)+1}^{a_{k(n,i)+1}} \cdots p_r^{a_r} \in Z(n, i) \) if \( r > k(n,i) \) Thus \( \#X(n, i) \leq \#Y(n, i) \cdot (\#Z(n, i) + 1) \). Now fix \( n \). If \( \#Z(n, i) < 2^{|i|} \) would hold for unboundedly many \( i \) then we would have \( \#X(n, i) \leq (n+3)^{k(n,i)} \cdot 2^{|i|} \) for unboundedly many \( i \).

This contradicts (1). Thus the existence of \( \mathcal{K}(n) \) follows. \( \square \)

In the next section we need some elementary result on the number of prime factors of elements of HR. Thus, following Hardy’s notation, let \( \Omega(a) \) for \( a \in \text{HR} \) denote the number of prime factors in \( a \) counted with multiplicities.

**Lemma 3** \( m \leq 2^{\Omega(m)^2} \) for \( m \in \text{HR} \).

The proof requires only simple estimates on the function \( j \mapsto p_j \) which may be found for example in Apostol [1976].

3 The classification result for Ackermannian functions

We call a primitive recursive function \( f : \mathbb{N}^k \to \mathbb{N} \) elementary if there is a \( K \) such that \( f(x_1, \ldots, x_k) \leq 2^k (x_1 + \cdots + x_k)^k \) for all \( x_1, \ldots, x_k \in \mathbb{N} \).

For any \( g : \mathbb{N}^2 \to \mathbb{N} \) let \( F_g(n) = \max \{ K : (\exists m_1, \ldots, m_K \in \text{HR})[m_1 \cdots m_K & \forall i \leq K[m_i \leq g(n, i)]] \} \).

According to a general result of Friedman and Sheard [1995] there exists an elementary function \( g : \mathbb{N}^2 \to \mathbb{N} \) such that \( H_{\omega^0}(n) \leq F_g(n) \) since the coding of \( \omega^0 \) via HR is elementary. A closer inspection of the coding of the fundamental sequences for \( \omega^0 \) yields that \( H_{\omega^0}(n) \leq F_g(n) \) for \( (n, i) = 2^{(n+2)/i} \).

In this section we are going to classify as good as seems possible the functions \( g \) for which \( H_{\omega^0}(n) \leq F_g(n) \) holds. For that purpose we use a result about special descent recursions where bounds on \( \Omega \) are put.

For a function \( g : \mathbb{N}^2 \to \mathbb{N} \) let \( G_g(n) = \max \{ K : (\exists m_1, \ldots, m_K \in \text{HR})[m_1 \cdots m_K & \forall i \leq K[\Omega(m_i) \leq g(n, i)] \} \). Then according to an unpublished result due to Friedman for \( q(n, i) = n + i \) there is a unary elementary function \( p(n) \) such that \( H_{\omega^0}(n) \leq G_g(p(n)) \) for every \( n \).
This result is not sharp enough for our application. We use the following refinement which follows from [Weiermann (2003)].

**Theorem 5** Let $q(n,i) := n + 1 + \sqrt{i}$. Then there is a unary elementary function $p(n)$ such that $H_{q^p}(n) \leq G_q(p(n))$ for every $n$.

The main result of this paper is now as follows.

**Theorem 6** Let $h(i) := H_{q^p}(i)$ and $g(n,i) = n + 2^\sqrt{i}$. Then there is an elementary recursive function $t(n)$ such that $H_{q^h}(n) \leq F_{g}(t(n))$ for every $n$.

**Proof.** Let $B(n) := G_q(n)$ where $g(n,i) = n + 1 + \sqrt{i}$. Without loss of generality we may prove the result for $B$ instead of $H_{q^h}$. Let $C := B^{-1}$ be the inverse function of $B$. Assume now that $n$ be given. Put $K := B(n)$. To show $K \leq F_{g}(t(n))$ for some elementary function $t$ we now have to find $n_1, \ldots, n_k$ in HR such that $n_1 \geq \ldots \geq n_k$ and $n_i \leq t(n) + 2^\sqrt{i}$ for $1 \leq i \leq K$.

According to Theorem 5 there are $m_1, \ldots, m_K \in HR$ such that $m_1 \geq \ldots \geq m_K$ and

$$\Omega(m_i) \leq n + 1 + \sqrt{i}$$

for $i \leq K$.

For $1 \leq i \leq K$ we have $C(i) \leq C(B(n)) = n$, hence $C(i + \sqrt{i}) \geq \sqrt{i}$ for $1 \leq i \leq K$. $\Omega(m_1) \leq n + 2$ yields $m_i \prec p^{n+2}$ for $2 \leq i \leq K$. Assume that for some function $k(n,i)$

$$m_i = p_{a_1}^{a_1} \cdots p_{a_k(n,i)}^{a_k(n,i)}$$

Then $a_{i1} \leq n + 1$ for $2 \leq i \leq K$ and $k(n,i) \leq n + 1 + \sqrt{i}$ by (2). Put

$$Z(n,i) = \{ a \in \mathbb{N} : a \leq 2^\sqrt{i} \text{ and } a = p_{a_{i1}}^{a_{i1}} \cdots p_{a_{k(n,i)}}^{a_{k(n,i)}} \}.$$ 

By Corollary 1 we obtain

$$\#Z(n,i) \geq 2^{|i|} \geq i$$

for $i \geq K(n)$. Put

$$n_i := p_{1}^{n+5} \cdot p_{2} \cdots p_{K(n)+1-i}$$

for $1 \leq i \leq K(n)$ and

$$n_i := p_{1}^{n+3+a_{i1}} \cdots p_{k(n,i)}^{n+3+a_{k(n,i)}} \cdot \text{enum}_{Z(n,i)}(2^{|i|} - i)$$

for $K(n) < i \leq K$ where enum$_{Z(n,i)}$ enumerates the elements of $Z(n,i)$ in increasing order with respect to $\prec$. This is well defined by (2). Moreover the $n_i$ are indeed $\prec$-decreasing.

Let $h(n) = p_{1}^{2n+5} \cdot p_{2} \cdots p_{K(n)+1}$. Then $n_i \leq h(n) + 2^\sqrt{i}$ for $1 \leq i \leq K(n)$.

A detailed investigation of the proof of Corollary 1 yields that the function $n \mapsto K(n)$ can be chosen elementary. This follows by inspection of the proof of Theorem 2 in [Hardy and Ramanujan (1916)], by inspection of the proof of Lemma 1 and an application of the effective version of Theorem 5 (cf. Theorem 9 of paragraph 7.4 in [Tenenbaum (1995)] page 227).

Therefore the function $h$ is elementary.
By elementary bounds on the function $j \mapsto p_j$ (see, for example, Apostol (1976)), we obtain a constant $D$ such that $l_j \leq \exp(D \ln(j))$ for all $j$. Thus for $K(n) \leq i \leq K$ we obtain using Lemma 3

$$n_i \leq \exp((n+2)Dk(n, |i|) \ln(k(n, |i|))) \cdot 2^{k(n, |i|)^2} \cdot 2^{\sqrt{2^{|i|}}},$$

for some suitable elementary function $t'$. Note that $k(n, |i|)$ disappears in the calculation since for large $i$ we have $k(n, |i|)^2 \leq (n + 1 + \sqrt{|i|})^2$ which is (for large $i$) much smaller than $n^2 \sqrt{2^{|i|}}$. This yields the claim.

The following shows that our bound is sharp.

**Theorem 7** Let $g_{\alpha}(n, i) = n + 2^{\alpha^{i-1}/2^{|i|}}$. Let $F_{g_{\alpha}}(n) = \max\{K : (\exists m_1, \ldots, m_K \in HR)[m_1 \succ \ldots \succ m_K & \forall i \leq K][m_i \leq g(n, i)]\}$. Then $F_{g_{\alpha}}$ is primitive recursive for all $\alpha < \omega^\omega$.

The proof is left as an exercise and can be extracted from Arai (2002) or Weiermann (2003) using Theorem 4.

**Remarks:** At first sight it seems that Theorems 6 and 7 are very special since they rely on the specific representation of the Hardy Ramanujan numbers, i.e. the specific coding of the ordinals below $\omega^\omega$. It turns out that they hold in much more general situations since the bounds from the Hardy Ramanujan, i.e. Theorem 2 can be extended cum grano salis to more general contexts. For example, if $f : \mathbb{N} \to \mathbb{N}$ is linear, i.e. $f(x) = k \cdot x$ for some fixed $k \in \mathbb{N}$ and if we consider

$$HR^f = \{p_{f(1)}^{a_1} \cdots p_{f(n)}^{a_n} : a_1 \geq \ldots \geq a_n \geq 1\}$$

then Theorems 6 and 7 hold also with respect to $HR^f$. Moreover we believe that it will be not too hard to show that Theorems 6 and 7 hold also with respect to $HR^f$ if $f : \mathbb{N} \to \mathbb{N}$ is a strictly increasing polynomial function. Moreover it seems plausible that it is possible to replace the data structure of primes by a suitable system of Beurling primes.

In this paper we have confined ourselves for the sake of simplicity of presentation with one of the most simplest choices of the coding. The coding seems to be a very natural one and it is in complete accordance with the choice proposed by Hardy and Ramanujan.
