String Pattern Avoidance in Generalized Non-crossing Trees

Yidong Sun and Zhiping Wang

Department of Mathematics, Dalian Maritime University, 116026 Dalian, P.R. China

The problem of string pattern avoidance in generalized non-crossing trees is studied. The generating functions for generalized non-crossing trees avoiding string patterns of length one and two are obtained. The Lagrange inversion formula is used to obtain the explicit formulas for some special cases. A bijection is also established between generalized non-crossing trees with special string pattern avoidance and little Schröder paths.

Keywords: Generalized non-crossing tree, pattern avoidance, Catalan number, little Schröder path

1 Introduction

A non-crossing tree (NC-tree for short) is a tree drawn on \( n \) vertices in \( \{1, 2, \ldots, n\} \) arranged in counterclockwise order along a circle such that the edges lie entirely within the circle and do not cross. Non-crossing trees have been investigated by Chen and Yan [1], Deutsch and Noy [3], Flajolet and Noy [4], Gu, et al. [5], Hough [6], Noy [7], Panholzer and Prodinger [8]. Recently, some problems of pattern avoidance in NC-trees have been studied by Sun and Wang [14]. It is well known that the set of NC-trees with \( n + 1 \) vertices is counted by the generalized Catalan number \( \frac{1}{2(n+1)} \binom{3n}{n} \) [12, A001764].

A generalized non-crossing tree (GNC-tree for short) is a generalization of ordinary non-crossing tree such that the vertices along the circle are not necessarily labelled by \( 1, 2, \ldots, n \), but only weakly increasing, beginning with 1 and without “gaps”. See Figure 2 for an example.

In the sequel, we are concerned with rooted GNC-trees where the first 1 is the root. Let \( \text{GNC}_n \) denote the set of rooted GNC-trees of \( n + 1 \) vertices. It is easy to prove that \( \text{GNC}_n \) is counted by \( |\text{GNC}_n| = \frac{2n}{2n+1} \binom{3n}{n} \) [12, A153231].

A descent (an ascent, a level) is an edge \((i, j)\) such that \( i > j \) (\( i < j, i = j \)) and \( i \) is on the path from the root to the vertex \( j \). If encoding an ascent by \( u \), a level by \( h \) and a descent by \( d \), then each path in a GNC-tree can be represented by a ternary word on \( \{u, h, d\} \) by reading the path from the root. In analogy with the well-established permutation patterns [11, 15], we propose a definition of patterns in GNC-trees. However, it should be pointed out that in the present paper we are dealing with “string pattern avoidance” (only consecutive letters are considered), which is thus different from “pattern avoiding” as defined in [11, 15].

1365–8050 c 2009 Discrete Mathematics and Theoretical Computer Science (DMTCS), Nancy, France
Definition 1.1 Let $w = w_1 w_2 \ldots w_n$ and $\sigma = \sigma_1 \sigma_2 \ldots \sigma_k$ be two ternary words on \{u, h, d\}. Then $w$ contains the string pattern $\sigma$ if it has a subword $w_{i+1} w_{i+2} \ldots w_{i+k}$ equal to $\sigma$ for some $0 \leq i \leq n - k$; otherwise $w$ is called $\sigma$-avoiding. A GNC-tree $T$ is called $\sigma$-avoiding if $T$ has no subpath (viewed from the root) encoded by $\sigma$.

Let $P_k$ denote the set of ternary words of length $k$ on \{u, h, d\}. For any $\sigma \in P_k$, let $\text{GNC}_n^m(\sigma)$ denote the set of GNC-trees in $\text{GNC}_n$ which contain the pattern $\sigma$ exactly $m$ times. For any nonempty subset $P \subset P_k$, $\text{GNC}_n(P)$ denotes the set of GNC-trees in $\text{GNC}_n$ which avoid all the patterns in $P$. A counterpart for GNC-trees to the analogous question for restricted permutations is the following question:

Question 1.2 Determine the cardinalities of $\text{GNC}_n(P)$ for $P \subset P_k$ and $\text{GNC}_n^m(\sigma)$ for $\sigma \in P_k$.

In the literature, two kinds of special NC-trees have been considered, namely non-crossing increasing trees and non-crossing alternating trees. Both of them are counted by the Catalan numbers $C_n = \frac{1}{n+1} \binom{2n}{n}$ [12, A000108]. A non-crossing increasing (alternating) tree is an NC-tree with the vertices on the path from the root 1 to any other vertex appearing in increasing (alternating) order. By our notation, a non-crossing increasing tree is a $d$-avoiding NC-tree and a non-crossing alternating tree is a \{uu, dd\}-avoiding NC-tree. Bijections between non-crossing alternating trees and Dyck paths have been presented in [13]. But for GNC-trees, it seems to be shed little light on this subject.

The contents of the paper (and also the methods used) are much closer to studies of “peaks, valleys, etc.” in Motzkin paths or Dyck paths [9, 10]. In this paper, we deal with several patterns and find the formulas for some special cases. A bijection is also established between GNC-trees with special pattern avoidance and little Schröder paths.

2 The patterns in $P_3$

For any $T \in \text{GNC}_n$, let $u(T), h(T), d(T)$ denote the number of ascents, levels and descents of $T$ respectively, then $u(T) + h(T) + d(T) = n$. Let $\text{GNC}_n^\ast$ be the set of GNC-trees $T$ in $\text{GNC}_n$ such that $T$ has only one vertex with label 1, that is, only the root has the label 1 and all other vertices have labels greater than 1. Define

$$
T_{x,y,z}(t) = \sum_{n \geq 0} t^n \sum_{T \in \text{GNC}_n} x^{u(T)} y^{h(T)} z^{d(T)},
$$

$$
T_{x,y,z}^\ast(t) = \sum_{n \geq 0} t^n \sum_{T \in \text{GNC}_n^\ast} x^{u(T)} y^{h(T)} z^{d(T)}.
$$

Close relations between $T_{x,y,z}(t)$ and $T_{x,y,z}^\ast(t)$ can be established using the “butterfly” decomposition (introduced by Flajolet and Noy [4]) of GNC-trees in Figure 1. It is obvious that the decomposition is only used for $n \geq 1$ and that the case $n = 0$ leads to the additional 1. Find the first and minimal label $i$, denoted by $\hat{i}$, of $T \in \text{GNC}_n$ in counterclockwise order such that the root 1 and $\hat{i}$ form an edge, then $T$ can be partitioned into three parts.

Case(i): $i = j = 1$ and $k = 1$ or 2. Part I and II both avoid the patterns $u$ and $d$, Part III still forms a GNC-tree. The edge $(1, 1)$ contributes a weight of $yt$, each of Part I and II contributes $T_{0,y,0}(t)$, and Part III contributes $T_{x,y,z}(t)$.
String Pattern Avoidance in Generalized Non-crossing Trees

Fig. 1: Decomposition of GNC-trees.

Case(ii): \( i = 1, j \geq 2 \) and \( k = j \) or \( j + 1 \). Part I avoids the patterns \( u \) and \( d \), Part II still forms a GNC-tree, where not all vertices are labeled by 1. The edge \((1,1)\) contributes a weight of \( yt \), Part I contributes \( T_{0,y,0}(t) \) and Part II contributes \( T_{x,y,z}(t) - T_{0,y,0}(t) \). For Part III, except for the one point case, by decreasing all the labels (excluding the root) by \( j - 2 \) units (if \( k = j \)) or \( j - 1 \) units (if \( k = j + 1 \)), one can obtain two GNC-trees in \( GNC_n^* \) for some \( n \geq 1 \). Part III contributes \( 2T_{x,y,z}^*(t) - 1 \).

Case(iii): \( i \geq 2, j \geq i \) and \( k = j \) or \( j + 1 \). The edge \((1,1)\) contributes a weight of \( xt \). Note that the ascents and descents are exchanged in Part I, and the labels are lying in \( \{1, 2, \ldots, i\} \) or \( \{2, 3, \ldots, i\} \), so Part I contributes \( 2T_{z,y,x}^*(t) - T_{0,y,0}(t) \) for \( i \geq 2 \). Part II still forms a GNC-tree after reducing the labels \( \{i, \ldots, j\} \) to \( \{1, \ldots, j-i+1\} \), so Part II contributes \( T_{x,y,z}(t) \). Similar to (ii), Part III contributes \( 2T_{x,y,z}^*(t) - 1 \).

In summary, we have

\[
T_{x,y,z}(t) = 1 + ytT_{0,y,0}(t)^2T_{x,y,z}(t) + xtT_{x,y,z}(t)\left\{2T_{x,y,z}^*(t) - 1\right\}.
\]  
\[\text{(2.1)}\]

For any \( T \in GNC_n^* \), by a similar decomposition, one can derive that

\[
T_{x,y,z}^*(t) = 1 + xtT_{x,y,z}(t)T_{z,y,x}(t)\left\{2T_{x,y,z}^*(t) - 1\right\}.
\]  
\[\text{(2.2)}\]

Now we solve (2.2) for \( T_{x,y,z}^*(t) \) and substitute into (2.1) to obtain

\[
T_{x,y,z}(t) = 1 - ytT_{0,y,0}(t)^2 - xtT_{x,y,z}(t)T_{0,y,0}(t) + ytT_{0,y,0}(t)\left\{1 + T_{0,y,0}(t)\right\}T_{x,y,z}(t)
+ 2xt\left\{1 - ytT_{0,y,0}(t)^2\right\}T_{x,y,z}(t)^2T_{z,y,x}(t).
\]  
\[\text{(2.3)}\]

If \( x = z = 0 \), then (2.3) reduces to

\[
T_{0,y,0}(t) = 1 + ytT_{0,y,0}(t)^3.
\]  
\[\text{(2.4)}\]
Multiplying on both sides of (2.3) by \(T_{0,y,0}(t)\) and using (2.4), after some routine computations, one can deduce that
\[
T_{x,y,z}(t) = 1 + (y - x)T_{0,y,0}(t)^2T_{x,y,z}(t) + 2xtT_{x,y,z}(t)^2T_{z,y,x}(t). \tag{2.5}
\]

The evaluation \(x = y = z = 1\) immediately gives \(T_{1,1,1}(t) = 1 + 2tT_{1,1,1}(t)^3\), which thus proves that \(|\text{GNC}_n| = \frac{n^2 + (\frac{3n}{2})}{2n+1}\) via generating functions. By solving (2.5) for \(T_{x,y,z}(t)\), we have
\[
T_{x,y,z}(t) = 1 - (y - x)T_{0,y,0}(t)^2 - \sqrt{(1 - (y - x)T_{0,y,0}(t)^2)^2 - 8xtT_{z,y,x}(t)}
\]
\[
= \frac{1}{1 - (y - x)T_{0,y,0}(t)^2} C\left(\frac{2xtT_{z,y,x}(t)}{1 - (y - x)T_{0,y,0}(t)^2}\right), \tag{2.6}
\]
where \(C(t) = \frac{1 - \sqrt{1 - 4t^2}}{2t}\) is the generating function for Catalan numbers.

Exchanging \(x\) and \(z\) in (2.6), one can compute \(T_{z,y,x}(t)\). If one substitutes the result in (2.6), one arrives at the following proposition.

**Proposition 2.1** The generating function \(T_{x,y,z}(t)\) for GNC-trees solves the third order equation
\[
2\alpha^2\beta x^2tT^3 + (\beta z - \alpha x)T^2 + (\alpha^2 x - 2\alpha\beta z)T + \alpha^2\beta z = 0,
\]
namely,
\[
T_{x,y,z}(t) = \alpha C\left(2xt\alpha^2\beta C\left(2zt\beta^2T_{x,y,z}(t)\right)\right),
\]
where \(\alpha = \frac{1}{1 - (y - x)T_{0,y,0}(t)^2}\) and \(\beta = \frac{1}{1 - (y - z)T_{0,y,0}(t)^2}\).

By the Lagrange inversion formula and some series expansions, one can obtain the coefficient of \(t^n\) of \(T_{x,y,z}(t)\), but it seems to be somewhat complicated. Now we will consider several special cases which lead to interesting results.

### 2.1 \(u\)-avoiding GNC-trees

Note that \(T_{0,y,z}(t)\) is the generating function for GNC-trees with no ascent. By setting \(x = 0\) in (2.5), one can find
\[
T_{0,y,z}(t) = 1 + ytT_{0,y,0}(t)^2T_{0,y,z}(t),
\]
from which, together with (2.4), and using the Lagrange inversion formula, one can deduce that
\[
T_{0,y,z}(t) = T_{0,y,0}(t) + \sum_{n \geq 0} \frac{1}{2n+1} \binom{3n}{n} (yt)^n = T_{0,1,0}(yt).
\]
In fact, the above relation can be easily derived from the definition of GNC-tree: since a \(u\)-avoiding GNC-tree must also avoid the pattern \(d\), such GNC-trees can be obtained by changing each label of the underlying NC-trees to the label 1.
2.2 \textit{h}-avoiding GNC-trees

Note that $T_{x,0,z}(t)$ is the generating function for GNC-trees with no level. By setting $y = 0$ in (2.4) and (2.5), one can find

$$T_{x,0,z}(t) = 1 - xtT_{x,0,z}(t) + 2xtT_{x,0,z}(t)^2T_{z,0,x}(t),$$

which, when $x = z = 1$, yields

$$T_{1,0,1}(t) = 1 - tT_{1,0,1}(t) + 2tT_{1,0,1}(t)^3.$$

Let $\lambda = T_{1,0,1}(t) - 1$, then $\lambda = t(1 + \lambda)(2(1 + \lambda)^2 - 1)$, using the Lagrange inversion formula [16], one can deduce for $n \geq 1$ that

$$[t^n]T_{1,0,1}(t) = \frac{1}{n} \sum_{i=0}^{n} (-1)^{n-i} \binom{n}{i} 2^i (\lambda^{n-1})(1 + \lambda)^{n+2i}.$$

This leads to the following result.

\textbf{Theorem 2.2} The set of \textit{h}-avoiding GNC-trees of $n + 1$ vertices is counted by

$$|\text{GNC}_n(h)| = \sum_{i=0}^{n} (-1)^{n-i} \frac{2^i}{2i+1} \binom{3i}{i} \binom{n+2i}{3i}.$$

This sequence beginning with 1, 1, 5, 31, 217, 1637, 12985 is listed in Sloane’s [12, A153232].

2.3 \textit{d}-avoiding GNC-trees

Note that $T_{x,y,0}(t)$ is the generating function for GNC-trees with no descent. By setting $z = 0$ in (2.6), we can find

$$T_{x,y,0}(t) = \frac{1}{1 - (y - x)tT_{0,y,0}(t)} C\left(\frac{2xtT_{0,y,x}(t)}{(1 - (y - x)tT_{0,y,0}(t)^2)^2}\right),$$

$$= \frac{1}{1 - (y - x)tT_{0,1,0}(yt)} C\left(\frac{2xtT_{0,1,0}(yt)}{(1 - (y - x)tT_{0,1,0}(yt)^2)^2}\right),$$

where we used the relation $T_{0,y,x}(t) = T_{0,y,0}(t) = T_{0,1,0}(yt)$.
Case i

Setting \( x = y = 1 \) in (2.7), one gets
\[
T_{1,1,0}(t) = C(2tT_{0,1,0}(t)).
\]

Taking the coefficient \( t^n \) of \( T_{1,1,0}(t) \), one gets
\[
[t^n]T_{1,1,0}(t) = [t^n]C(2tT_{0,1,0}(t)) = [t^n]\sum_{i \geq 0} 2^i C_i t^i T_{0,1,0}(t)^i
\]
\[
= [t^n]\sum_{i \geq 0} 2^i C_i t^i \sum_{j \geq 0} \frac{i}{3j+i} \binom{3j+i}{j} t^j,
\]
\[
= \sum_{i+j=n} \frac{i}{3j+i} \binom{3j+i}{j} 2^i C_i.
\]

This leads to the following results.

**Theorem 2.3** The set of \( d \)-avoiding GNC-trees of \( n+1 \) vertices is counted by
\[
|\text{GNC}_n(d)| = \sum_{i+j=n} \frac{i}{3j+i} \binom{3j+i}{j} 2^i C_i.
\]

This sequence beginning with 1, 2, 10, 62, 424, 3070 is not listed in Sloane’s [12].

Case ii

Setting \( y = 1 \) in (2.7), by (2.4), one gets
\[
T_{x,1,0}(t) = \frac{T_{0,1,0}(t)}{1 + xtT_{0,1,0}(t)} C\left(\frac{2xtT_{0,1,0}(t)^3}{(1 + xtT_{0,1,0}(t))^2}\right).
\]

Taking the coefficient \( t^n x^k \) of \( T_{x,1,0}(t) \), one gets
\[
[t^n x^k]T_{x,1,0}(t) = [t^{n-k} x^k] \frac{T_{0,1,0}(t)}{1 + xtT_{0,1,0}(t)} C\left(\frac{2xtT_{0,1,0}(t)^3}{(1 + xtT_{0,1,0}(t))^2}\right)
\]
\[
= [t^{n-k}] \sum_{i=0}^{k} 2^i C_i T_{0,1,0}(t)^{3i+1} \left[x^{k-i} \frac{1}{(1 + xtT_{0,1,0}(t))^{2i+1}}\right]
\]
\[
= \sum_{i=0}^{k} 2^i C_i (-1)^{k-i} \binom{k+i}{k-i} [t^{n-k}]T_{0,1,0}(t)^{k+2i+1}
\]
\[
= \sum_{i=0}^{k} (-1)^{k-i} \binom{k+i}{k-i} \frac{k+2i+1}{3n-2k+2i+1} \binom{3n-2k+2i+1}{n-k} 2^i C_i.
\]

This leads to the following results.

**Theorem 2.4** The set of \( d \)-avoiding GNC-trees of \( n+1 \) vertices with \( k \) ascents is given by
\[
\sum_{i=0}^{k} (-1)^{k-i} \binom{k+i}{k-i} \frac{k+2i+1}{3n-2k+2i+1} \binom{3n-2k+2i+1}{n-k} 2^i C_i.
\]
Case iii

Setting \( x = 1 \), \( y = 0 \) in (2.7) and using \( T_{0,0,0}(t) = T_{0,1,0}(0) = 1 \), one gets

\[
T_{1,0,0}(t) = \frac{1}{1 + t} C(\frac{2t}{(1 + t)^2}) = \frac{1 + t - \sqrt{1 - 6t + t^2}}{4t},
\]

which is the generating function for little Schröder paths. Recall that a little Schröder path of length \( 2n \) is a lattice path in the first quadrant running from \((0, 0)\) to \((2n, 0)\) consisting of up steps \( U = (1, 1) \), down steps \( D = (1, -1) \) and horizontal steps \( H = (2, 0) \) with no horizontal step at the \( x \)-axis. Let \( \mathcal{S}_n \) denote the set of little Schröder paths of length \( 2n \) which is counted by the \( n \)th little Schröder number \( s_n \) [12, A001003], whose generating function is \( S(t) = \frac{1 + t - \sqrt{1 - 6t + t^2}}{4t} \).

![Diagram](image1.png)

![Diagram](image2.png)

![Diagram](image3.png)

Fig. 2: The bijection between \( \text{GNC}_n(h, d) \) and \( \mathcal{S}_n \).

**Theorem 2.5** The set of \( \{h, d\} \)-avoiding (i.e. increasing) GNC-trees of \( n + 1 \) vertices is counted by the \( n \)th little Schröder number. There exists a bijection between \( \text{GNC}_n(h, d) \) and \( \mathcal{S}_n \).
3 \ The patterns in $P_2$

Define $\text{GNC}_n^*(P)$ to be the set of GNC-trees in $\text{GNC}_n^*$ avoiding any $\sigma$ in a set $P$ of patterns. For any $\sigma \in P_2$, define

$$T_{x,y,z}^\sigma(t) = \sum_{n \geq 0} t^n \sum_{T \in \text{GNC}_n^*(\sigma)} x^{u(T)} y^{h(T)} z^{d(T)},$$

$$T_{x,y,z}^{\ast\sigma}(t) = \sum_{n \geq 0} t^n \sum_{T \in \text{GNC}_n^*(\sigma)} x^{u(T)} y^{h(T)} z^{d(T)}.$$

In this section, we deal with the patterns $uu, dd, ud$ and $du$, the others can be investigated similarly.

3.1 \ The patterns $uu$ and $dd$.

Close relations between $T_{x,y,z}^{uu}(t)$ and $T_{x,y,z}^{\ast uu}(t)$ can be established using the decomposition of GNC-trees in Figure 1.

Case(i): $i = j = 1$ and $k = 1$ or 2. Part I and II both avoid the patterns $u$ and $d$, Part III still forms a $uu$-avoiding GNC-tree. Then the edge $(1,1)$ contributes a weight of $yt$, each of Part I and II contributes $T_{0,y,0}(t)$, and Part III contributes $T_{x,y,z}^{uu}(t)$.

Case(ii): $i = 1, j \geq 2$ and $k = j$ or $j + 1$. Part I avoids the patterns $u$ and $d$, Part II still forms a $uu$-avoiding GNC-tree, where not all vertices are labeled by 1. Then the edge $(1,1)$ contributes a weight of $yt$, Part I contributes $T_{0,y,0}(t)$ and Part II contributes $T_{x,y,z}^{uu}(t) - T_{0,y,0}(t)$. For Part III, except for the one point case, decreasing all the labels (excluding the root), by $j - 2$ units if $k = j$ or by $j - 1$ units if $k = j + 1$, one can obtain two $uu$-avoiding GNC-trees in $\text{GNC}_n^*(uu)$ for some $n \geq 1$. Then Part III contributes $2T_{x,y,z}^{\ast uu}(t) - 1$.

Case(iii): $i \geq 2, j \geq i$ and $k = j$ or $j + 1$. The edge $(1,1)$ contributes a weight of $xt$. Note that the ascents and descents are exchanged in Part I, and the labels are lying in $\{1,2,\ldots,i\}$ or $\{2,3,\ldots,i\}$, so Part I contributes $2T_{x,y,z}^{dd}(t)$ - $T_{0,y,0}(t)$. But Part II can not begin with a $u$ edge, i.e., all edges (if exist) starting form $(i,i)$ are $h$ edges, so we should further partition Part II into three parts, by finding the last vertex labeled $i$, which we denote by $i^*$, in counterclockwise order such that $(i,i^*)$ is an $h$ edge which contributes a weight of $yt$, see Figure 3. Clearly, Part II$_1$ and II$_2$ both contribute $T_{0,y,0}(t)$, and Part II$_3$ contributes $T_{x,y,z}^{uu}(t)$. Similar to (ii), Part III contributes $2T_{x,y,z}^{\ast uu}(t) - 1$. 

**Proof:** For any $T \in \text{GNC}_n(h,d)$, traversing its edges from the root, when an edge $(i,j)$ is first read, we have a $U$-step and mark the $U$-step by $j$; When an edge is read in the second time, we have a $D$-step. Then we get a little Schröder path with no $H$-step (In fact a Dyck path). For any $U$-step in the Dyck path, find the maximal segment of $D$-steps followed the $U$-step and mark all of the $D$-steps with the same label as the $U$-step. For any two consecutive steps $DU$ (In fact a valley), if they have the same label, then replace them by an $H$-step and remove the remaining labels, which leads to the desired little Schröder path.

It is clear that the above procedure is invertible, see Figure 2 for an example. 

□

3. The patterns in $P_2$
respectively by (3.3). After some simplifications, one obtains

\[ T_{x,y,z}(t) = 1 + ytT_{0,y,0}(t)^2T_{x,y,z}(t) + ytT_{0,y,0}(t)\left\{ T_{x,y,z}(t) - T_{0,y,0}(t) \right\} \left\{ 2T_{x,y,z}(t) - 1 \right\} 
+ xt \left\{ 2T_{x,y,z}(t) - T_{0,y,0}(t) \right\} \left\{ 1 + ytT_{0,y,0}(t)^2T_{x,y,z}(t) \right\} \left\{ 2T_{x,y,z}(t) - 1 \right\} \]  \hspace{1cm} (3.1)

For any \( T \in \text{GNC}^*_n(\text{uu}) \), by the similar decomposition, one can easily derive that

\[ T^*_{x,y,z}(t) = 1 + xtT^*_{x,y,z}(t)\left\{ 1 + ytT_{0,y,0}(t)^2T^*_{x,y,z}(t) \right\} \left\{ 2T^*_{x,y,z}(t) - 1 \right\} . \]  \hspace{1cm} (3.2)

Similarly, for the pattern \( \text{dd} \), close relations between \( T^\text{dd}_{x,y,z}(t) \) and \( T^*_{x,y,z}(t) \) can be established using the decomposition of GNC-trees in Figure 1, the details are omitted.

\[ T^\text{dd}_{x,y,z}(t) = 1 + ytT_{0,y,0}(t)^2T^\text{dd}_{x,y,z}(t) + ytT_{0,y,0}(t)\left\{ T^\text{dd}_{x,y,z}(t) - T_{0,y,0}(t) \right\} \left\{ 2T^\text{dd}_{x,y,z}(t) - 1 \right\} 
+ xt \left\{ 2T^\text{uu}_{x,y,z}(t) - T_{0,y,0}(t) \right\} T^\text{dd}_{x,y,z}(t) \left\{ 2T^\text{dd}_{x,y,z}(t) - 1 \right\} . \]  \hspace{1cm} (3.3)

\[ T^*_{x,y,z}(t) = 1 + xtT^*_{x,y,z}(t)T^\text{dd}_{x,y,z}(t) \left\{ 2T^*_{x,y,z}(t) - 1 \right\} . \]  \hspace{1cm} (3.4)

Solve (3.2) for \( T^*_{x,y,z}(t) \) and (3.4) for \( T^\text{dd}_{x,y,z}(t) \), and then substitute them respectively into (3.1) and (3.3). After some simplifications, one obtains

\[ T^\text{uu}_{x,y,z}(t) = \left\{ 1 - xtT_{0,y,0}(t)^2 + 2xtT^\text{uu}_{x,y,z}(t)T^\text{dd}_{x,y,z}(t) \right\} \left\{ 1 + ytT_{0,y,0}(t)^2T^\text{uu}_{x,y,z}(t) \right\} , \] \hspace{1cm} (3.5)

\[ T^\text{dd}_{x,y,z}(t) = 1 + (y-x)tT_{0,y,0}(t)^2T^\text{dd}_{x,y,z}(t) + 2xtT^\text{dd}_{x,y,z}(t)T^\text{uu}_{x,y,z}(t) . \] \hspace{1cm} (3.6)

Setting \( x = y = z = 1 \) in (3.5) and (3.6), we have

**Proposition 3.1** The generating functions for uu-avoiding and dd-avoiding GNC-trees are determined respectively by

\[ T^\text{uu}_{1,1,1}(t) = \left\{ 1 - t0_{1,0}(t)^2 + 2tT^\text{uu}_{1,1,1}(t)T^\text{dd}_{1,1,1}(t) \right\} \left\{ 1 + t0_{1,0}(t)^2T^\text{uu}_{1,1,1}(t) \right\} , \]

\[ T^\text{dd}_{1,1,1}(t) = 1 + 2tT^\text{dd}_{1,1,1}(t)T^\text{uu}_{1,1,1}(t) . \]
When \(x = z = 1, y = 0\), by \(T_{0,0,0}(t) = 1\), (3.5) and (3.6) generate

\[
T_{1,0,1}^{uu}(t) = 1 - t + 2tT_{1,0,1}^{uu}(t)T_{1,0,1}^{dd}(t),
T_{1,0,1}^{dd}(t) = 1 - tT_{1,0,1}^{dd}(t) + 2T_{1,0,1}^{dd}(t)T_{1,0,1}^{uu}(t),
\]

from which, one can deduce that

\[
T_{1,0,1}^{uu}(t) = \frac{1 - t}{1 - 2tT_{1,0,1}^{dd}(t)},
(3.7)
\]

\[
T_{1,0,1}^{dd}(t) = 1 - 3tT_{1,0,1}^{dd}(t) + 4t^2T_{1,0,1}^{dd}(t)^2.
(3.8)
\]

From (3.7) and (3.8), one can get

\[
T_{1,0,1}^{dd}(t) = \frac{1 + 3t - \sqrt{(1 + 3t)^2 - 16t^2}}{8t} = \frac{1 + 3t}{4}C\left(\frac{4t}{(1 + 3t)^2}\right) = \sum_{i \geq 0} \frac{4^i C_i t^i}{(1 + 3t)^{2i+1}}
\]

\[
= \sum_{i \geq 0} 4^i C_i t^i \sum_{j \geq 0} (-1)^j \binom{2i + j}{j} 3^j t^j
\]

\[
= \sum_{n \geq 0} t^n \sum_{j=0}^n (-1)^j \binom{2n - j}{j} 3^j 4^{n-j} C_{n-j}.
\]

\[
T_{1,0,1}^{uu}(t) = \frac{1 - t}{1 - 2tT_{1,0,1}^{dd}(t)} = \frac{3 - 3t - \sqrt{(1 + 3t)^2 - 16t^2}}{2}
\]

\[
= \frac{3(1 - t) - \sqrt{(1 - t)^2 - 8t(1 - t)}}{2}
\]

\[
= 1 - 2t C\left(\frac{2t}{1 - t}\right) = 1 + t + \sum_{i \geq 0} \frac{2^{i+2} C_{i+1} t^{i+2}}{(1 - t)^{i+1}}
\]

\[
= 1 + t + \sum_{n \geq 0} t^{n+2} \sum_{i=0}^n \binom{n}{i} 2^{i+2} C_{i+1}.
\]

This leads to the following results.

**Theorem 3.2** The sets \(\text{GNC}_{n+2}(uu, h)\) of \(\{uu, h\}\)-avoiding GNC-trees and \(\text{GNC}_n(dd, h)\) of \(\{dd, h\}\)-avoiding GNC-trees are counted respectively by

\[
|\text{GNC}_{n+2}(uu, h)| = \sum_{i=0}^n \binom{n}{i} 2^{i+2} C_{i+1},
\]

\[
|\text{GNC}_n(dd, h)| = \sum_{j=0}^n (-1)^j \binom{2n - j}{j} 3^j 4^{n-j} C_{n-j}.
\]
The case $x = y = z = 1$ in (3.13) and (3.14) yields the following result.

**Proposition 3.4** The generating functions for $ud$-avoiding and $du$-avoiding GNC-trees are given by

$$
T_{x,y,z}^{ud}(t) = 1 + 2tT_{0,0,0}(t)^2T_{1,1,1}(t),
$$
$$
T_{x,y,z}^{du}(t) = 1 + 2tT_{0,0,0}(t)^2T_{1,1,1}(t).
$$

When $x = z = 1, y = 0$, by $T_{0,0,0}(t) = 1$, (3.13) and (3.14) generate

$$
T_{1,1,0}^{ud}(t) = 1 - tT_{1,0,0}(t) + 2tT_{1,0,0}(t)^2,
$$
$$
T_{1,1,0}^{du}(t) = 1 - tT_{1,0,0}(t) + 2tT_{1,0,0}(t)^2T_{1,0,1}(t),
$$
from which, one can deduce that

\[ T^{ud}_{1,0,1}(t) = \frac{1 + t - \sqrt{1 - 6t + t^2}}{4t} = \frac{1 + t}{1 + t} C\left(\frac{2t}{(1 + t)^2}\right), \]

\[ T^{du}_{1,0,1}(t) = \frac{1 + t - \sqrt{(1 + t)^2 - 8tS(t)}}{4S(t)} \]

\[ = \frac{1}{1 + t} C\left(\frac{2tS(t)}{(1 + t)^2}\right) = \sum_{i \geq 0} \frac{2^i C_i}{(1 + t)^{2i+1}} \]

\[ = \sum_{i \geq 0} \frac{2^i C_i t^i}{(1 + t)^{2i+1}} \sum_{j \geq 0} \frac{i}{2j + 1} \left(\frac{2j + i}{j}\right) \]

\[ = \sum_{n \geq 0} \sum_{i+j+k=n} (-1)^k \left(\frac{3i + 2j + k}{k}\right) \frac{i}{2j + 1} \left(\frac{2j + i}{j}\right) 2^{i+j} C_i. \]

This leads to the following result.

**Theorem 3.5** The set \( GNC_n(ud, h) \) of \( \{ud, h\}\)-avoiding (i.e. increasing) GNC-trees is counted by the \( n \)th little Schröder number, and the set \( GNC_n(du, h) \) of \( \{du, h\}\)-avoiding GNC-trees is counted by

\[ |GNC_n(du, h)| = \sum_{i+j+k=n} (-1)^k \left(\frac{3i + 2j + k}{k}\right) \frac{i}{2j + 1} \left(\frac{2j + i}{j}\right) 2^{i+j} C_i. \]

This sequence beginning with 1, 1, 5, 27, 157, 957, 6025 is listed in [12, A153233].

### 3.3 The pattern \( \{uu, dd\} \)

Now we consider the pattern \( \{uu, dd\} \), let \( P = \{uu, dd\} \), using the decomposition of GNC-trees, relations between \( T^P_{x,y,z}(t) \) and \( T^P_{x,y,z}(t) \) can be derived, the details are omitted:

\[ T^P_{x,y,z}(t) = 1 + yt_{0,0,0}(t)T^P_{x,y,z}(t) + yt_{0,0,0}(t)\left\{T^P_{x,y,z}(t) - T_{0,0,0}(t)\right\}\left\{2T^P_{x,y,z}(t) - 1\right\}, \]

\[ + xt\left\{2T^P_{x,y,z}(t) - T_{0,0,0}(t)\right\}\left\{1 + yt_{0,0,0}(t)T^P_{x,y,z}(t)\right\}\left\{2T^P_{x,y,z}(t) - 1\right\}, \]

\[ T^P_{x,y,z}(t) = 1 + xtT^P_{x,y,z}(t)\left\{1 + yt_{0,0,0}(t)T^P_{x,y,z}(t)\right\}\left\{2T^P_{x,y,z}(t) - 1\right\}, \]

from which, one can get

\[ T^P_{x,y,z}(t) = \left\{1 + yt_{0,0,0}(t)T^P_{x,y,z}(t)\right\}\left\{1 - xt_{0,0,0}(t)^2 + 2xtT^P_{x,y,z}(t)T^P_{x,y,z}(t)\right\}. \]  \hspace{1cm} (3.15)

The case \( x = y = z = 1 \) in (3.15) yields

**Proposition 3.6** The generating function for \( \{uu, dd\}\)-avoiding GNC-trees is given by

\[ T^P_{1,1,1}(t) = \left\{1 + t_{0,0,0}(t)^2T^P_{1,1,1}(t)\right\}\left\{1 - t_{0,0,0}(t)^2 + 2tT^P_{1,1,1}(t)^2\right\}. \]
String Pattern Avoidance in Generalized Non-crossing Trees

Setting \(y = 0\) in (3.15), by \(T_{0,0,0}(t) = 1\), one can get

\[
T_{x,0,z}(t) = 1 - xt + 2xtT_{x,0,z}^P(t)T_{x,0,z}^P(t). \tag{3.16}
\]

Exchanging \(x\) and \(z\) in (3.16), one has

\[
T_{x,0,z}^P(t) = 1 - zt + 2ztT_{x,0,z}^P(t)T_{x,0,z}^P(t). \tag{3.17}
\]

From (3.16) and (3.17), one can obtain

\[
T_{x,0,z}(t) = 1 - xt - 2(z - x)T_{x,0,z}^P(t) + 2ztT_{x,0,z}^P(t)^2,
\]

which leads to

\[
T_{x,0,z}(t) = 1 + 2(z - x)t - \frac{\sqrt{(1 + 2(z - x)t)^2 - 8zt(1 - xt)}}{4zt}. \tag{3.18}
\]

Setting \(z = 1\) in (3.18), one can deduce

\[
T_{x,0,1}(t) = \frac{1 - x t - \sqrt{(1 + 2(1 - x)t)^2 - 8t(1 - xt)}}{4t} = \frac{1 - xt}{1 + 2(1 - x)t}C(\frac{2t(1 - xt)}{1 + 2(1 - x)t})^{2i+1}
\]

\[
= \sum_{i \geq 0} 2^i C_i t^i \sum_{j=0}^{i+1} (-1)^j \binom{i+1}{j} x^{i-j} \sum_{k \geq 0} (-1)^k \binom{2i + k}{k} 2^k t^k \sum_{\ell=0}^k (-1)^\ell \binom{k}{\ell} x^\ell.
\]

Setting \(x = z = 1\) in (3.18), one has

\[
T_{1,0,1}(t) = \frac{1 - \sqrt{1 - 8t(1 - t)}}{4t} = (1 - t)C(2t(1 - t))
\]

\[
= \sum_{n \geq 0} t^n \sum_{i=0}^{n} (-1)^{n-i} \binom{i+1}{n-i} 2^i C_i,
\]

which leads to the following result.

**Theorem 3.7** The number of \{\(uu, dd, h\)\}-avoiding (i.e., alternating) GNC-trees of \(n + 1\) vertices is given by

\[
\sum_{i=0}^{n} (-1)^{n-i} \binom{i+1}{n-i} 2^i C_i, \quad ([12, A068764]).
\]

Moreover, the number of alternating GNC-trees of \(n + 1\) vertices with exactly \(r\) ascents is

\[
\sum_{i+j+k=n} (-1)^{r+k} \binom{i+1}{j} \binom{2i + k}{k} \binom{k}{r-j} 2^{i+k} C_i.
\]
**Remark 3.8** When \( r = 0 \), then \( j = 0 \) and there is no alternating GNC-tree of \( n + 1 \) vertices with exactly \( r = 0 \) ascents for \( n \geq 1 \). So we have

\[
\sum_{i=0}^{n} (-1)^{n-i} \binom{n+i}{n-i} C_i = 0, \quad (n \geq 1).
\]

When \( x = -1, z = 1 \) in (3.18), one has

\[
T_{1,0,1}^{P}(t) = \frac{1 + 4t - \sqrt{1 + 8t^2}}{4t} = 1 - tC(-2t^2)
\]

\[
= 1 + \sum_{n \geq 0} (-1)^{n+1} 2^n C_n t^{2n+1},
\]

which leads to the following results.

**Theorem 3.9** The difference between the number of alternating GNC-trees on \( m \) vertices with an even number of ascents and those with an odd number of ascents is zero if \( m = 2n + 3 \) and \((-1)^{n+1} 2^n C_n \) if \( m = 2n + 2 \) for \( n \geq 0 \).
