The Eulerian distribution on centrosymmetric involutions

Marilena Barnabei and Flavio Bonetti and Matteo Silimbani

Università di Bologna - Dipartimento di Matematica

We present an extensive study of the Eulerian distribution on the set of centrosymmetric involutions, namely, involutions in $S_n$ satisfying the property $\sigma(i) + \sigma(n+1-i) = n+1$ for every $i = 1 \ldots n$. We find some combinatorial properties for the generating polynomial of such distribution, together with an explicit formula for its coefficients. Afterwards, we carry out an analogous study for the subset of centrosymmetric involutions without fixed points.

Keywords: involution, permutation statistic, Eulerian distribution, hyperoctahedral group.

1 Introduction

The distribution of the descent statistic (classically known as Eulerian distribution) on peculiar subsets of permutations has been object of intensive studies in recent years. In particular, several authors examined the properties of the polynomial $I_n(x) = \sum_{j=0}^{n-1} i_{n,j} x^j$, where $i_{n,j}$ denotes the number of involutions on $[n] = \{1, 2, \ldots, n\}$ with $j$ descents. More specifically, in (13) V. Strehl proved that the coefficients of this polynomial are symmetric, and recently V.J. Guo and J. Zeng (5) showed that the polynomial $I_n(x)$ is unimodal. In a previous paper (2) the present authors proved that the polynomial $I_n(x)$ is not log-concave.

The calculation involved in founding a counterexample to this property is based on a (not bijective) correspondence between involutions on $[n]$ with $j$ descents and generalized involutions on length $n$ on $m$ symbols, with $m > j$. This correspondence yields an explicit formula for the coefficients $i_{n,j}$ of the polynomial $I_n(x)$.

In this paper we study the polynomial $S_n(x) = \sum_{j=0}^{n-1} s_{n,j} x^j$, where $s_{n,j}$ denotes the number of centrosymmetric involutions on $[n]$ with $j$ ascents (and hence $n - 1 - j$ descents).

We say that $\sigma \in S_n$ is a centrosymmetric permutation if $\sigma(i) + \sigma(n+1-i) = n+1$ for every $i = 1, \ldots, n$.

We observe that the group consisting of centrosymmetric permutations in $S_{2k}$ is isomorphic to the hyperoctahedral group $B_k$, namely, the group of permutations of the set $\{-k, \ldots, 1, \ldots, k\}$ such that $\sigma(i) = -\sigma(-i)$.

Centrosymmetric involutions appear in many different contexts. For instance, it is well known (see \cite{11} and \cite{7} for more details) that an involution $\sigma$ is centrosymmetric if and only if the Young tableau $P$ corresponding to $\sigma$ via the Robinson–Schensted algorithm is fixed under the Schützenberger map. Moreover, the permutation matrix associated with a centrosymmetric involution is both symmetric and centrosymmetric. The descent statistic on the set of centrosymmetric involutions is equivalent to the statistic $f_{\text{des}}(\sigma)$ introduced in \cite{1} for the hyperoctahedral group.

First of all, we exhibit an explicit formula and a recursive rule for the total number of centrosymmetric involutions on $[n]$. Then, following along the lines of \cite{2}, we obtain some enumerative results for the sequence $s_{n,j}$ by exploiting a map that associates a centrosymmetric involution with a suitable set of generalized involutions. In particular, we deduce an explicit formula for the integers $s_{n,j}$, which allows us to prove that the polynomials $I_n(x)$ and $S_n(x)$ share some properties, such as the symmetry of the coefficients and the non log-concavity.

The last section is devoted to the study of the Eulerian distribution on centrosymmetric involutions without fixed points. Also in this case, we find an explicit formula for the number $s^*_{n,j}$ of centrosymmetric involutions on $[n]$ without fixed points and $j$ ascents. The main result of this section is the proof of the symmetry $s^*_{2k,d} = s^*_{2k,2k-d-2}$, based on the proof of the analogous result for all fixed point free involutions due to V. Strehl \cite{13}. Since Strehl’s proof does not appear in the cited paper, we decided to describe it in full detail at the end of this paper.

2 Preliminary notions

In this section, we give some definitions and general results about involutions and generalized involutions.

We recall that the descent set of a permutation $\sigma$ is defined as $\text{Des}(\sigma) = \{1 \leq i < n : \sigma(i) > \sigma(i + 1)\}$. An analogous definition can be given for the ascent set $\text{Asc}(\sigma)$ of a permutation, by replacing "$\sigma(i) > \sigma(i + 1)$" with "$\sigma(i) < \sigma(i + 1)$".

Given a Ferrers diagram $\lambda$, a (dual) semistandard tableau of shape $\lambda$ over the alphabet $[m]$ is an array obtained by placing into each box of the diagram $\lambda$ an integer in $[m]$ so that the entries are strictly increasing by rows and weakly increasing by columns.

There are many different bijections between pairs of tableaux of the same shape and suitable two-lines arrays, that are based on the classical Robinson–Schensted-Knuth procedure (see \cite{6}). These procedures differ in the definition of the insertion rule and the characterization of the two-line array involved. In the following, we will use the variation described below that concerns pairs of dual semistandard tableaux.

A generalized permutation is defined to be a biword:

$$\alpha = \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} x_1 & x_2 & \cdots & x_n \\ y_1 & y_2 & \cdots & y_n \end{pmatrix},$$
such that:

• $x_i \leq x_{i+1}$,

• $x_i = x_{i+1} \implies y_i \geq y_{i+1}$.

The integer $n$ is called the length of the generalized permutation $\alpha$. The word $x = x_1 \cdots x_n$ is called the $x$-content of $\alpha$ and, similarly, the word $y = y_1 \cdots y_n$ is called the $y$-content of $\alpha$.

A generalized involution will be a generalized permutation $\alpha$ satisfying the further condition that each pair $(a_b)$ occurs as many times as the pair $(b_a)$. In this case, the $x$-content and the $y$-content of $\alpha$ coincide and we will call each of them the content of $\alpha$.

We associate a generalized permutation with a pair $(P, Q)$ of dual semistandard tableaux as follows. The tableau $P$ is obtained from the empty tableau by inserting the sequence $y_1, \ldots, y_n$ in accordance with the following variation of the row-insertion procedure. Suppose that we inserted the symbols $y_{i-1}, \ldots, y_1$, obtaining the tableau $P_{i-1}$. Then, we insert $y_i$ in the tableau $P_{i-1}$, getting the tableau $P_i$ as follows

• if $y_i$ is strictly greater than each symbol in the first row of $P_{i-1}$, add $y_i$ in a new box to the end of the first row;

• otherwise, find the left-most entry in the first row of $P_{i-1}$ that is larger than or equal to $y_i$. Put the symbol $y_i$ in the box of this entry, and remove the entry. Take this entry and repeat the process on the second row.

The tableau $Q$ is obtained, as usual, filling the box $b_i$ created at the $i$-th step with the integer $x_i$.

The above procedure appears in [3], Section 3 (see also [8], subsect. 4.4). It is easy to check that, when we apply this procedure to a generalized involution, we obtain a pair $(P, Q)$, where $P = Q$.

We recall that the standardization map $\Pi$ associates with a generalized permutation

$$\alpha = \begin{pmatrix} x_1 & x_2 & \cdots & x_n \\ y_1 & y_2 & \cdots & y_n \end{pmatrix},$$

the permutation

$$\Pi(\alpha) = \begin{pmatrix} 1 & 2 & \cdots & n \\ y_1' & y_2' & \cdots & y_n' \end{pmatrix},$$

where $y_i' = 1$ if $y_i$ is the least symbol occurring in the word $y$, $y_j' = 2$ if $y_j$ is the second least symbol in $y$ and so on. In the case $y_i = y_j$, with $i > j$, we consider $y_i$ to be less then $y_j$.

Note that the polarization of a generalized involution is an involution, since the above given rule for handling the case $y_i = y_j$ is coherent with the rule for the ordering of biletters in a generalized permutation.

For example, the standardization of the generalized involution

$$\alpha = \begin{pmatrix} 1 & 1 & 2 & 3 & 4 & 4 & 4 & 6 \\ 4 & 3 & 2 & 1 & 6 & 4 & 1 & 4 \end{pmatrix}$$
is the involution
\[ \Pi(\alpha) = \begin{pmatrix}
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\
7 & 4 & 3 & 2 & 8 & 6 & 1 & 5
\end{pmatrix}. \]
Note that the map \( \Pi \) is not injective, since, for any given involution \( \sigma \), there are infinitely many generalized involutions whose standardization is \( \sigma \). For example, the generalized involution
\[ \beta = \begin{pmatrix}
1 & 1 & 1 & 3 & 4 & 4 & 5 & 6 \\
5 & 3 & 1 & 1 & 6 & 4 & 1 & 4
\end{pmatrix} \]
has the same standardization as \( \alpha \) in the previous example (i.e., \( \Pi(\alpha) = \Pi(\beta) \)).

We will denote by \( \text{Gen}_m(\sigma) \) the set of generalized involutions, with symbols taken from \([m]\), whose standardization is \( \sigma \). Observe that two generalized involutions in \( \text{Gen}_m(\sigma) \) can not have the same content. For this reason the set \( \text{Gen}_m(\sigma) \) corresponds bijectively with the set of contents of its elements.

We will say that a content \( x \) is compatible with \( \sigma \) if there exists a generalized involution in \( \text{Gen}_m(\sigma) \) whose content is \( x \), for some \( m \).

It is easy to check that a content \( x = x_1 \cdots x_n \) is compatible with an involution \( \sigma \) if and only if
\[ i \in \text{Asc}(\sigma) \implies x_i < x_{i+1}. \]

The key tool in the present paper is the interplay between involutions and generalized involutions. For this reason we need to evaluate the cardinality of the set \( \text{Gen}_m(\sigma) \), for any given involution \( \sigma \). It turns out that this cardinality depends only on the number of ascents of \( \sigma \). In fact, denoting by \( \mathcal{I}_n \) the set of involutions in \( S_n \), we have the following result, formerly stated in [2]:

**Proposition 1** Let \( \sigma \in \mathcal{I}_n \) be an involution with \( t \) ascents. Then,
\[ |\text{Gen}_m(\sigma)| = \binom{n + m - t - 1}{n}. \]  

**Proof:** Choose an involution \( \sigma \in \mathcal{I}_n \) with \( t \) ascents. As we remarked above, the set \( \text{Gen}_m(\sigma) \) corresponds bijectively to the set of contents \( x = x_1 \cdots x_n \) with \( 1 \leq x_1 \leq x_2 \leq \cdots \leq x_n \leq m \), where the inequalities are strict at places corresponding to the ascents of \( \sigma \). Every such content is uniquely determined by the sequence \( \delta := \delta_0 \delta_1 \cdots \delta_n \), with
\[ \delta_0 = x_1 - 1, \quad \delta_1 = x_2 - x_1, \quad \ldots, \quad \delta_n = m - x_n \]
which is a (weak) composition of the integer \( m - 1 \) such that its \( i \)-th component \( \delta_i \) is at least one whenever \( \sigma \) has an ascent at the \( i \)-th position. For this reason we can consider the word \( \delta' = \delta'_0, \delta'_1, \ldots, \delta'_n \) defined as follows:
\[ \delta'_i = \begin{cases} 
\delta_i - 1 & \text{if } \sigma \text{ has an ascent at the } i \text{-th position} \\
\delta_i & \text{otherwise}
\end{cases}, \]
which is a composition of the integer \( m - t - 1 \) in \( n + 1 \) parts. This gives the assertion. \( \square \)
3 Centrosymmetric involutions

We say that a permutation $\sigma \in S_n$ is centrosymmetric whenever $\sigma(i) + \sigma(n + 1 - i) = n + 1$ for every $i = 1, \ldots, n$. For instance, the permutation $\sigma = 3 \ 5 \ 1 \ 6 \ 2 \ 4$ is centrosymmetric, while $\sigma' = 3 \ 4 \ 6 \ 2 \ 1 \ 5$ is not centrosymmetric because, for instance, $\sigma'(1) + \sigma'(6) = 8 \neq 7$.

In other terms, a permutation $\sigma \in S_n$ is centrosymmetric if and only if it commutes with the involution $\psi \in S_n$ defined by $\psi(i) = n + 1 - i$.

When $n = 2k$, the set $C_{2k}$ of centrosymmetric permutations on $2k$ objects is a subgroup of $S_{2k}$ isomorphic to the hyperoctahedral group $B_k$ via the map $\Theta : C_{2k} \to B_k$ that associates a permutation $\sigma \in C_{2k}$ with the signed permutation $\Theta(\sigma)$ defined by:

$$\Theta(\sigma)(i) = \begin{cases} 
\sigma(k + i) - k & \text{if } \sigma(k + i) > k \\
\sigma(k + i) - k - 1 & \text{otherwise}
\end{cases}$$

For example, if $\sigma = 2 \ 1 \ 6 \ 5 \ 4 \ 3 \ 8 \ 7$, then we have $\Theta(\sigma) = -1 \ 2 \ 4 \ 3$.

If $n = 2k + 1$, for every $\sigma \in C_{2k+1}$, we must have $\sigma(k + 1) = k + 1$ by definition. Hence, a permutation in $C_{2k+1}$ is associated to the unique permutation in $C_{2k}$ obtained by deleting the central symbol.

We denote by $J_n$ the subset of $C_n$ consisting of centrosymmetric involutions. Note that the classical complementation and reversal maps $c : \sigma \mapsto \psi \sigma \quad r : \sigma \mapsto \sigma \psi$ coincide when restricted to the set $J_n$. These two bijections map centrosymmetric involutions to centrosymmetric involutions, while the whole set of involutions in not closed under such maps.

It is well known (see, e.g., [6] and [11]) that centrosymmetric involutions correspond via the Robinson–Schensted bijection to standard Young tableaux that are fixed under the Schützenberger map (evacuation). In fact, this map can be described in terms of involutions as $\sigma \mapsto ev(\sigma) = \psi \sigma \psi$.

We now introduce some notation concerning the cycle decomposition of centrosymmetric involutions. Recall that $\sigma$ is an involution if and only if its disjoint cycle decomposition consists uniquely of fixed points and transpositions. We will say that the transposition $\tau = (i, j)$ divides $\sigma$, in symbols $\tau \mid \sigma$, whenever $\tau$ appears in the cycle decomposition of $\sigma$. We will say that $(i, j)$ is a smooth transposition of $S_n$ if $i \neq n + 1 - j$. In this language, we have:

**Proposition 2** An involution $\sigma \in J_n$ is centrosymmetric if and only if the following two conditions hold:

$$\sigma(i) = i \iff \sigma(n + 1 - i) = n + 1 - i,$$

$$\tau \mid \sigma \iff (n + 1 - i, n + 1 - j) \mid \sigma.$$
Note that Proposition 2 implies that, whenever a transposition \( \tau \) divides an involution \( \sigma \), this forces four values of \( \sigma \) if \( \tau \) is smooth, and two values otherwise.

Denote by \( s_n \) the cardinality of the set \( \mathcal{S}_n \). By previous considerations, \( s_{2k} = s_{2k+1} \). Hence, we restrict our attention to the even case.

The sequence \( s_{2k} \) satisfies the following well known recurrence (see, e.g., (10)):

**Theorem 3** We have:

\[
s_{2k} = 2s_{2k-2} + (2k-2)s_{2k-4}
\]

The characterization given in Proposition 2 allows us to give an explicit formula for the integers \( s_{2k} \):

**Theorem 4** The number of centrosymmetric involutions on \( 2k \) symbols is

\[
s_{2k} = \sum_{h=0}^{\lfloor \frac{k}{2} \rfloor} \frac{(2k)!!}{(k-2h)!h!2^h}.
\]

**Proof:** Fix an integer \( h \leq \lfloor \frac{k}{2} \rfloor \). We count the number of involutions in \( \mathcal{S}_{2k} \) with exactly \( 2h \) smooth transpositions. Choose a word \( w = w_1 \cdots w_k \) consisting of \( k \) different letters taken from the alphabet \([2k]\) such that \( w \) does not contain simultaneously an integers \( i \) and its complement \( 2k + 1 - i \). We have \( (2k)(2k-2) \cdots (2) = (2k)!! \) choices for such a word. This word corresponds to a unique centrosymmetric involution \( \tau \) with \( 2h \) smooth transpositions defined by the following conditions:

\[
\tau(w_1) = w_2, \ldots, \tau(w_{2h-1}) = w_{2h};
\]

\[
\tau(w_{2h+j}) = \begin{cases} w_{2h+j} & \text{if } w_{2h+j} \leq k \\ 2k + 1 - w_{2h+j} & \text{otherwise} \end{cases},
\]

with \( 0 < j \leq k - 2h \). It is easily checked that the involution \( \tau \) arises from \( (k-2h)!h!2^h2^h \) different words \( w \). This completes the proof. \( \square \)

## 4 Centrosymmetric generalized involutions

We recall that the Schützenberger map can be extended to semistandard tableaux (see, for instance, (12)). In terms of generalized involution, this map can be described as follows: the image of the generalized involution

\[
\alpha = \begin{pmatrix} x_1 & x_2 & \cdots & x_n \\ y_1 & y_2 & \cdots & y_n \end{pmatrix}
\]

over the alphabet \([m]\) is the generalized involution

\[
ev(\alpha) = \begin{pmatrix} m + 1 - x_n & m + 1 - x_{n-1} & \cdots & m + 1 - x_1 \\ m + 1 - y_n & m + 1 - y_{n-1} & \cdots & m + 1 - y_1 \end{pmatrix}.
\]
A generalized involution $\alpha$ is said to be centrosymmetric whenever $\alpha = ev(\alpha)$, namely,
\[
  x_i + x_{n+1-i} = y_i + y_{n+1-i} = m + 1
\]
for every $i = 1 \ldots n$.

From now on, extending the previous notation, we will write $\binom{i}{j}|\alpha$ with multiplicity $s$ whenever the pair $\binom{i}{j}$ appears exactly $s$ times in the generalized involution $\alpha$. Also in this case, we will say that $\binom{i}{j}$ is a smooth transposition if $i \neq m + 1 - j$ and $i \neq j$. Obviously, if $\binom{i}{j}$ is a smooth transposition of the generalized involution $\alpha$, also $\binom{j}{i}$ is a smooth transposition of $\alpha$ (with the same multiplicity). Moreover:

**Proposition 5** A generalized involution $\alpha$ is centrosymmetric if and only if, whenever $\binom{i}{j}|\alpha$ with multiplicity $s$, we have also $\binom{m+1-i}{m+1-j}|\alpha$ with the same multiplicity. $\square$

Proposition 5 yields a further characterization of centrosymmetric generalized involutions, which will be useful in the following sections.

**Proposition 6** A generalized involution $\alpha$ is centrosymmetric if and only if it satisfies the following properties:

- the content $x = x_1 \ldots x_n$ of $\alpha$ is symmetric, namely $x_i + x_{n+1-i} = m + 1$,
- the standardization $\Pi(\alpha)$ of $\alpha$ is a centrosymmetric involution.

We denote by $c_{n,m}$ the number of generalized involutions of length $n$ over the alphabet $[m]$.

Setting $n = 2k + 1$, straightforward considerations lead to the following properties:

- if $m = 2h$, $c_{2k+1,m} = 0$;
- if $m = 2h + 1$, the central pair $\frac{(2h+1)}{h+1}$ of every centrosymmetric generalized involution of length $n$ over the alphabet $[m]$ is necessarily the pair $\frac{h+1}{h+1}$. This implies that $c_{2k+1,m} = c_{2k,m}$.

Hence, the values of the sequences $c_{2k+1,m}$ can derived from the sequences $c_{2k,m}$. For this reason we restrict our considerations to the even case.

**Theorem 7** The number of centrosymmetric generalized involutions of length $2k$ over $[m]$ is:

\[
  c_{2k,m} = \sum_{j=0}^{[\frac{m}{2}]} \left( \binom{m}{j} - \left\lfloor \frac{m}{2} \right\rfloor \right) \left( \binom{k}{j} + 1 \right) \left( \binom{m + k - 2j - 1}{k - 2j} \right). \tag{5}
\]

**Proof:** Fix $h \leq \left\lfloor \frac{m}{2} \right\rfloor$. We count centrosymmetric generalized involutions of length $2k$ over $[m]$ symbols with exactly $2h$ smooth transpositions which, in the present case, can or can not be different. The set $A$ of all possible smooth transposition has cardinality

\[
  \binom{m}{2} - \left\lfloor \frac{m}{2} \right\rfloor.
\]
Observe that, given a generalized involution $\alpha$ and a smooth transposition $\tau = (i)$, we have that $\tau|\alpha$ with multiplicity $s$ if and only if $\tau'|\alpha$ with the same multiplicity, where $\tau' = (i+1-1)$. It is evident that $\tau$ can be chosen in $\binom{n}{2} - \left\lfloor \frac{m}{2} \right\rfloor$ ways. Every such choice determines four pairs of $\alpha$. The remaining $2k - 4h$ pairs can be chosen to be either fixed points or non-smooth transpositions. This completes the proof.

Hence, the column generating function of the array $c_{2k,m}$ is

$$
\sum_{k \geq 0} c_{2k,m} x^k = \frac{1}{(1-x)^m(1-x^2)^{\binom{n}{2} - \left\lfloor \frac{m}{2} \right\rfloor}}.
$$

Note that the expression of this generating function is closely similar to the classical expression of the analogous generating function of generalized involutions $a_{n,m}$ or, equivalently, of semistandard tableaux (see (9)):

$$
\sum_{n \geq 0} a_{n,m} x^n = \frac{1}{(1-x)^m(1-x^2)^{\binom{m}{2}}}.
$$

5 The Eulerian distribution on centrosymmetric involutions

We now study the distribution of the ascent statistic on the set of centrosymmetric involutions. The combinatorial relations between involutions and generalized involutions pointed out in the previous section will play a crucial role for this analysis.

The distribution of the ascent statistic on the set of involutions behaves properly with respect to the action of the Schützenberger map. In fact:

**Proposition 8** For every involution $\sigma \in \mathcal{I}_{2k}$, we have:

$$|\text{Asc}(\sigma)| = |\text{Asc}(\text{ev}(\sigma))|.$$

Moreover, the ascent sets $\text{Asc}(\sigma)$ and $\text{Asc}(\text{ev}(\sigma))$ are mirror symmetric, i.e. $\sigma$ has an ascent at position $i$ if and only if $\text{ev}(\sigma)$ has an ascent at position $2k - i$.

**Proof:** Suppose that $\sigma$ has an ascent at position $i$, namely, $\sigma(i) < \sigma(i+1)$. Then,

$$
\text{ev}(\sigma)(2k - i) = \text{ev}(\sigma)(2k + 1 - (i + 1)) = 2k + 1 - \sigma(i + 1) < 2k + 1 - \sigma(i) = \text{ev}(\sigma)(2k + 1 - i),
$$

as desired. \qed

For example, let

$$
\sigma = \begin{pmatrix}
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\
5 & 7 & 8 & 6 & 1 & 4 & 2 & 3
\end{pmatrix},
$$
where, from now on, the bold-faced numbers denote the ascent positions. Then,
\[ ev(\sigma) = \left( \begin{array}{cccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\ 6 & 7 & 5 & 8 & 3 & 1 & 2 & 4 \end{array} \right). \]

The sets \( \text{Asc}(\sigma) = \{1, 2, 5, 7\} \) and \( \text{Asc}(ev(\sigma)) = \{1, 3, 6, 7\} \) are mirror symmetric (as defined before).

In particular, if \( \sigma \) is a centrosymmetric involution on \( 2k \) objects, then its ascent set must be mirror symmetric with respect to the \( k \)-th entry.

We are now interested in finding an explicit formula for the number \( s_{2k,d} \) of centrosymmetric involutions with \( d \) ascents. First of all, we have:

**Proposition 9** The sequence \( s_{2k,d} \) is symmetric, namely,
\[ s_{2k,i} = s_{2k,2k-1-i}. \]

**Proof:** Given a centrosymmetric involution \( \sigma \), it is easily checked that the permutation \( \psi \sigma \) satisfies the following properties:

- \( \psi \sigma \) is an involution;
- \( \psi \sigma \) is centrosymmetric;
- \( \psi \sigma \) has a descent at position \( i \) whenever \( \sigma \) has an ascent at the same position.

Hence, the function \( \sigma \mapsto \psi \sigma \) maps an involution with \( i \) ascents into an involution with \( 2k - 1 - i \) ascents.

For example, let
\[ \sigma = \left( \begin{array}{cccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\ 1 & 7 & 5 & 6 & 3 & 4 & 2 & 8 \end{array} \right). \]

Then,
\[ \psi \sigma = \left( \begin{array}{cccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\ 8 & 2 & 4 & 3 & 6 & 5 & 7 & 1 \end{array} \right). \]

The preceding result shows that the integer \( s_{2k,d} \) counts simultaneously the involutions in \( \mathcal{S}_{2k} \) with \( d \) descents and those with \( d \) ascents.
Now we want to express the number $c_{2k,m}$ of centrosymmetric generalized involutions of length $2k$ over $[m]$ in terms of the sequence $s_{2k,d}$ by exploiting the combinatorial relations between involutions and generalized involutions. As in the general case (Proposition 1), it turns out that the number of centrosymmetric generalized involutions on $m$ symbols whose standardization is a given involution $\sigma$, namely, belonging to the set $Gen_m(\sigma)$, depends only on the number of ascents of $\sigma$. In fact:

**Theorem 10** We have:

$$c_{2k,m} = \sum_{j=0}^{m-1} \left( k + \left\lfloor \frac{j}{2} \right\rfloor \right) s_{2k,m-1-j}.$$  \hspace{1cm} (6)

**Proof:** Let $\sigma \in \mathcal{I}_2k$ be a centrosymmetric involution with $t$ ascents. We want to determine the number of centrosymmetric elements in the set $Gen_m(\sigma)$. Combining Proposition 6 and the arguments used in the proof of Proposition 1, we deduce that such elements correspond bijectively to those compositions $\delta'$ of the integer $m-1-t$ into $2k+1$ parts which are centrosymmetric, namely, such that $\delta'_{k-i} = \delta'_{k+i}$. Each one of these compositions $\delta'$ is determined as soon as we:

- choose an integer $h \leq \left\lfloor \frac{m-1-t}{2} \right\rfloor$,
- choose a composition $\eta = \eta_0\eta_2\ldots\eta_{k-1}$ of $h$ into $k$ parts;

The composition $\delta' = \delta'_0, \delta'_1, \ldots, \delta'_{2k}$ is now obtained as follows:

$$\delta' = \eta_0, \eta_1, \ldots, \eta_{k-1}, \delta'_k, \eta_{k-1}, \ldots, \eta_1, \eta_0,$$

where $\delta'_{k+1} = m-1-t-2h$.

Hence, the number of such compositions is

$$\sum_{h=0}^{\left\lfloor \frac{m-1-t}{2} \right\rfloor} \binom{h+k-1}{k-1} = \binom{\left\lfloor \frac{m-1-t}{2} \right\rfloor + k}{k}.$$  \hspace{1cm} (7)

By setting $j = m-1-t$, we get the assertion. \hfill \square

Identity (6) yields the following expression for the row generating function of the array $c_{2k,m}$:

$$\sum_{m \geq 1} c_{2k,m} x^m = \sum_{m \geq 1} \sum_{j=0}^{m-1} \left( k + \left\lfloor \frac{j}{2} \right\rfloor \right) s_{2k,m-1-j} x^m = \frac{x + x^2}{(1-x^2)^{k+1}} \sum_{j \geq 0} s_{2k,j} x^j.$$

We now exploit the described combinatorial relation between involutions and generalized involutions to determine an explicit formula for $s_{2k,d}$.

**Theorem 11** The number of centrosymmetric involutions of length $2k$ with $d$ ascents is:

$$s_{2k,d} = \sum_{j=1}^{d+1} (-1)^{d+1-j} \binom{d+1-j}{j} \left( k + \left\lfloor \frac{j}{2} \right\rfloor \right) \sum_{i=0}^{\left\lfloor \frac{j}{2} \right\rfloor} \left( \frac{(j-i-1)}{2} + i - 1 \right) \left( \frac{j+k-i-1}{k-2i} \right).$$  \hspace{1cm} (7)
Proof: Formula (6) shows that, for every fixed integer $k$, the vector $(c_{2k,1}, \ldots, c_{2k,2k})$ can be expressed as the product of a lower triangular matrix $M(k)$ and the vector $(s_{2k,0}, \ldots, s_{2k,2k-1})$, where
\[ M(k)_{ij} = \left( k + \left\lfloor \frac{i-j}{2} \right\rfloor \right) \left\lfloor \frac{i-j}{2} \right\rfloor, \]
for $i \geq j$. The matrix $M(k)$ is invertible, since it is lower triangular with unitary diagonal. The matrix $M(k)^{-1}$ can be easily computed and used to express the vector $(s_{2k,0}, \ldots, s_{2k,2k-1})$ in terms of $(c_{2k,1}, \ldots, c_{2k,2k})$ as follows:
\[ s_{2k,d} = \sum_{j=1}^{d+1} (-1)^{\left\lfloor \frac{d+j}{2} \right\rfloor + 1} \left( k + \left\lfloor \frac{j}{d+1-j} \right\rfloor \right) c_{2k,j}. \] (8)
Combining Formulae (5) and (8), we derive (7). □

Formula (7) allows to check that the polynomials $S_{2k}(x) = \sum_{j=0}^{2k-1} s_{2k,j} x^j$ are not, in general, log-concave, since we have, for example:
\[ s_{6,0} \cdot s_{6,2} = 37 > 36 = s_{6,1}^2. \]

In the case of centrosymmetric involutions on an odd number of symbols, the Eulerian distribution can be computed as follows:

**Proposition 12**

\[ s_{2k+1,d} = \begin{cases} 1 & \text{if } d = 0 \\ 0 & \text{if } d \text{ is odd} \\ s_{2k,d-1} + s_{2k,d} & \text{otherwise} \end{cases} \]

Proof: We recall that an involution $\sigma$ in $S_{2k+1}$ is obtained from a unique involution $\sigma'$ in $S_{2k}$ by adding the fixed point $k+1$ and renormalizing the remaining symbols. In doing this, either the central ascent of $\sigma'$ is changed into two ascents of $\sigma$ if $\sigma'$ has an odd number of ascents, or the number of ascents remains unchanged. □

The first values of $s_{n,d}$ are shown in the following table:

These first values lead to the belief that the polynomials $S_{2k}(x)$ are unimodal for every $k \in \mathbb{N}$. It would be interesting to find a combinatorial proof of this property.

6 Centrosymmetric involutions without fixed points

In this section we extend the study of the Eulerian distribution to the set of centrosymmetric involutions on $[n]$ without fixed points. Obviously, such involutions exist only if $n$ is even.

Denote by $\mathcal{S}^*_{2k}$ the set of centrosymmetric involutions on $2k$ objects without fixed points and by $s^*_{2k}$ the cardinality of $\mathcal{S}^*_{2k}$. Then:

**Theorem 13** We have:

$$s^*_{2k} = \sum_{h=0}^{\lfloor \frac{k}{2} \rfloor} \frac{k!}{(k-2h)!h!},$$

and

$$s^*_{2k} = s^*_{2k-2} + (2n-2)s^*_{2k-4}.$$  \hspace{1cm} (10)

**Proof:** We count centrosymmetric involutions without fixed points with exactly $2h$ smooth transpositions, $2h \leq k$. Choose a word $w = w_1 \cdots w_k$ consisting of $k$ different letters taken from the alphabet $1, \ldots, 2k$ such that $w$ does not contain simultaneously the integers $i$ and $2k + 1 - i$. We have $(2k)!$ choices for such a word. This word corresponds to a unique centrosymmetric involution $\tau$ without fixed points with $2h$ smooth transpositions defined by the following conditions:

$$\tau(w_1) = w_2, \ldots, \tau(w_{2h-1}) = w_{2h},$$

$$\tau(w_{2h+j}) = 2k + 1 - w_{2h+j}, \text{ for } 0 < j \leq k - 2h.$$

It is easily checked that the involution $\tau$ arises from $$(k-2h)!h!2^h2^{k-2h}.\text{ This gives Formula (9).}$$

Let now $\sigma \in \mathcal{S}^*_{2k}$. If $\sigma(1) = 2k$, and hence $\sigma(2k) = 1$, the restriction of $\sigma$ to the set $\{2, \ldots, 2k-1\}$ is a centrosymmetric involution on $2k - 2$ symbols without fixed points. If $\sigma(1) = j$, with $j < 2k$, the symbol $1$ is involved in a smooth transposition, hence we must have $\sigma(j) = 1, \sigma(2k + 1 - j) = 2k$ and $\sigma(2k) = 2k + 1 - j$. Then, the restriction of $\sigma$ to the set $\{2, \ldots, 2k-1\} \setminus \{j, 2k + 1 - j\}$ is a centrosymmetric involution on $2k - 4$ symbols without fixed points. Observing that there are $2k - 2$ possible choices for the integer $j$, we get (10).

\[\square\]

We point out that the proof of Theorems 13 suggests constructive rules for generating centrosymmetric involutions without fixed points.

Denote by $s^*_{2k,d}$ the number of involutions in $\mathcal{S}^*_{2k}$ with $d$ ascents. Once more, in order to find an explicit formula for the integers $s^*_{2k,d}$, we need to set up a connection between centrosymmetric involutions without fixed points and a suitable set of generalized involutions.

First of all, let $\alpha$ be a generalized involution. We say that the integer $a$ is a fixed point of multiplicity $r$ if

$$x_1 = y_1 = x_{i+1} = y_{i+1} = \cdots = x_{i+r-1} = y_{i+r-1} = a.$$
It is easy to see that each fixed point of the standardization $\Pi(\alpha)$ corresponds to a fixed point $a$ of $\alpha$ of odd multiplicity. Hence we must consider the set of centrosymmetric generalized involutions with fixed points of even multiplicity. Denote by $c^*_{2k,m}$ the number of such involutions of length $2k$ over the alphabet $[m]$. Then:

**Theorem 14** We have:

$$c^*_{2k,m} = \sum_{j=0}^{\left\lfloor \frac{m}{2} \right\rfloor} \left( \frac{\left( \frac{m}{2} \right) + \left\lfloor \frac{m}{2} \right\rfloor}{2j} + j - 1 \right) \left( \left\lfloor \frac{m}{2} \right\rfloor + k - 2j - 1 \right).$$

(11)

**Proof:** Fix $j \leq \left\lfloor \frac{m}{2} \right\rfloor$. We count the number of centrosymmetric generalized involutions of length $2k$ on the alphabet $[m]$ containing only fixed points of even multiplicity, such that exactly $4j$ of its pairs are either smooth transpositions or non central fixed points. A *non central fixed point* is an occurrence of a pair $(i, i)$ in $\alpha$, with $i \neq \frac{m+1}{2}$. Observe that, if $(i, h)$ is a smooth transposition of the generalized involution $\alpha$, then $\alpha$ must contain the four pairs $(i, h)$, $(h, i)$, $(m+1-i, h)$, and $(m+1-i, i)$. Moreover, if $(i, i)$ is a non central fixed point of $\alpha$, then $\alpha$ must contain two occurrences of the pair $(i, i)$ (in order to be fixed point free), and two occurrences of the pair $(m+1-i, i)$. Hence, if we want $\alpha$ to contain exactly $4j$ among smooth transpositions and non central fixed points, it is sufficient to choose $j$ (not necessarily distinct) pairs $(i, h)$ with $i \leq h$ and $i < \frac{m+1}{2}$. There are

$$\frac{\left( \frac{m}{2} \right) + \left\lfloor \frac{m}{2} \right\rfloor}{2}$$

such pairs.

The remaining pairs must be chosen to be either central fixed points or non smooth transpositions. This completes the proof. □

Repeating the same arguments as in the proofs of Theorems 10 and 11, we obtain the following result:

**Theorem 15** We have:

$$c^*_{2k,m} = \sum_{j=0}^{m-1} \left( k + \left\lfloor \frac{m}{2} \right\rfloor \right) s^*_{2k,m-1-j}.$$  

(12)

**Hence:**

$$s^*_{2k,d} = \sum_{j=1}^{d+1} (-1)^{d+1-i} \left( \frac{d-i+1}{2} \right) \left( \frac{k}{d+1-j} \right) \left( \left\lfloor \frac{m}{2} \right\rfloor + \left\lfloor \frac{m}{2} \right\rfloor \right) \left( \left\lfloor \frac{m}{2} \right\rfloor + k - 2i - 1 \right).$$

(13)

The next table contains the first values of the sequences $s^*_{2k,d}$:

</table>
This table shows that the polynomial \( S_{2k}^*(x) \) is not in general unimodal, and hence not log-concave.

These values suggest that the Eulerian distribution on centrosymmetric involutions without fixed points has the following symmetry:

\[
S_{2k,d}^* = S_{2k,2k-2-d}^*. \tag{14}
\]

The analogous symmetry of the Eulerian distribution on the whole set of centrosymmetric involutions has been proved exploiting the map \( \sigma \mapsto \psi \sigma \) (see Proposition 9). In this case, this approach fails, since this map does not preserve fixed point freeness. The last part of this section is devoted to the proof of such symmetry.

Denote by \( I_{2k}^* \) the set of fixed point free involutions in \( S_{2k} \) and by \( i_{2k,d}^* \) the number of fixed point free involutions in \( S_{2k} \) with \( d \) ascents. The symmetry of the ascent distribution on involutions without fixed point

\[
i_{2k,d}^* = i_{2k,2k-2-d}^*. \tag{15}\]

is a well known result due to Strehl (13). In fact, (13) is the summary of a talk given at the first session of Séminaire Lotharingien de Combinatoire and does not contain any proof. For this reason, we describe in full detail Strehl’s arguments, communicated to us by the author.

Strehl’s proof of Identity (15) is based on a bijection \( \theta \) that maps an involution in \( I_{2k}^* \) with \( d \) ascents into an involution in \( I_{2k}^* \) with \( 2k - d - 2 \) ascents. Identity (14) will be proved as soon as we show that the bijection \( \theta \) preserves centrosymmetry.

In order to define the map \( \theta \) we need some preliminaries. We recall that a permutation \( \sigma \) has an \textit{excedence} at position \( i \) whenever \( \sigma(i) > i \). Denote by \( R^\sigma \) the set of all excedences and by \( C^\sigma \) the set of all non excedences of \( \sigma \). Of course, if \( \sigma \in I_{2k}^* \), both these two sets have cardinality \( k \).

We associate with a given \( \sigma \in I_{2k}^* \) a path \( D_\sigma \) defined as follows: the \( i \)-th step of \( D_\sigma \) is an up-step if \( i \in R^\sigma \), a down-step otherwise. Since \( \sigma \in I_{2k}^* \), such a path is easily seen to be a Dyck path. Observe that the map \( \sigma \mapsto D_\sigma \) is not injective. We denote by \( I_{2k}^{\sharp \sigma} \) the set of all involutions in \( I_{2k}^* \) with a given associated Dyck path \( D \). The Dyck path \( D \) can be written as:

\[
D = U^{r_1}D^c_1U^{r_2}D^c_2 \ldots U^{r_p}D^c_p.
\]

The set of up-steps \( U^{r_i} \) will be called the \( i \)-th \textit{rise} of the Dyck path \( D \) and, similarly, the set of down-steps \( D^{c_j} \) the \( j \)-th \textit{fall} of \( D \). We associate with \( D \) two families of sets \( R_1, \ldots, R_p, C_1, \ldots, C_p \), as follows: the integer \( x \) belongs to \( R_i \) (respectively \( C_j \)) whenever the \( x \)-th step of \( D \) belongs to the \( i \)-th rise (resp. \( j \)-th fall) of \( D \). Obviously, we have:

\[
R = \bigcup_{1 \leq i \leq p} R_i \quad C = \bigcup_{1 \leq j \leq p} C_j,
\]

\[
|R_i| = r_i \quad |C_j| = c_j.
\]

If \( \sigma \in I_{2k}^{\sharp \sigma} \), we denote by \( \rho_i^\sigma \) the restriction of the permutation \( \sigma \) to the set \( R_i \). Clearly, we have:

\[
\rho_i^\sigma : R_i \rightarrow \bigcup_{i \leq j \leq p} C_j.
\]
Similarly, we denote by $\gamma_j^\sigma$ the restriction of the permutation $\sigma$ to the set $C_j$:

$$\gamma_j^\sigma : C_j \to \bigcup_{1 \leq i \leq j} R_i.$$  

Note that the involution $\sigma$ is completely determined by the Dyck path $D$ and the maps $\rho_i^\sigma$. In the following, if $\sigma$ is clear from the context, we will omit the symbol $\sigma$ in the previous notation.

We consider the further (possibly empty) sets

$$R_{ij} = \sigma(C_j) \cap R_i,$$

$$C_{ij} = \sigma(R_i) \cap C_j,$$

and denote by

$$\rho_{ij} : R_{ij} \to C_{ij},$$

$$\gamma_{ij} : C_{ij} \to R_{ij},$$

the restrictions of the maps $\rho_i$ and $\gamma_j$ to the domains indicated. Note that these maps are bijections.

For example, consider the involution in $I_{16}^*$

$$\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16 \\ 11 & 5 & 9 & 10 & 2 & 8 & 16 & 6 & 3 & 4 & 1 & 13 & 12 & 15 & 14 & 7 \end{pmatrix}.$$  

The Dyck path associated with $\sigma$ is the path in Figure 1 and we have:

![Fig. 1: The Dyck path associated with $\sigma$.](image-url)

$$R = \{1, 2, 3, 4, 6, 7, 12, 14\} \quad C = \{5, 8, 9, 10, 11, 13, 15, 16\},$$

$$R_1 = \{1, 2, 3, 4\} \quad R_2 = \{6, 7\} \quad R_3 = \{12\} \quad R_4 = \{14\},$$

$$C_1 = \{5\} \quad C_2 = \{8, 9, 10\} \quad C_3 = \{13\} \quad C_4 = \{15, 16\},$$

and the non empty $R_{ij}$ and $C_{ij}$ associated with $\sigma$ are:

$$R_{1,1} = \{2\} \quad R_{1,2} = \{1, 3, 4\} \quad R_{2,2} = \{6\} \quad R_{2,4} = \{7\} \quad R_{3,3} = \{12\} \quad R_{4,4} = \{14\},$$
Now define three bijections $\theta_1, \theta_2, \theta_3 : I^*_2 \to I^*_2$, as follows:

- if $\sigma \in I^*_2$, its image $\theta_1(\sigma)$ is the unique element of $I^*_2$ associated with the Dyck path $\mathcal{D}_\sigma$ and such that:
  \[ \rho_i^{\theta_1(\sigma)} = \rho_i^{\sigma} \circ \text{rev}_{R_i}, \]
  where, given a linearly ordered set $A = \{a_1, \ldots, a_n\}$, $\text{rev}_A : A \to A$ is the correspondence that maps the element $a_i$ into $a_{n+1-i}$.

- if $\sigma \in I^*_2$, its image $\theta_2(\sigma)$ is the unique element of $I^*_2$ associated with the Dyck path $\mathcal{D}_\sigma$ and such that:
  \[ \gamma_j^{\theta_2(\sigma)} = \gamma_j^{\sigma} \circ \text{rev}_{C_j}, \]

- the definition of the map $\theta_3$ is more complicated than the previous two and requires some preliminary notions.

Given a permutation $\tau$ corresponding via the Robinson–Schensted algorithm to the pair $(P, Q)$ of standard Young tableaux, denote by $\delta(\tau)$ the unique permutation associated with the pair of transposed tableaux $(P^T, Q^T)$. The map $\tau \mapsto \delta(\tau)$ will be called the transposition map.

For every $\sigma \in I^*_2$, its image $\theta_3(\sigma)$ is the unique element of $I^*_2$ such that:

\[
R_{ij}^{\theta_3(\sigma)} = R_{ij}^\sigma, \\
C_{ij}^{\theta_3(\sigma)} = C_{ij}^\sigma, \\
\rho_{ij}^{\theta_3(\sigma)} = \delta(\rho_{ij}^\sigma),
\]

for every $1 \leq i, j \leq p$, where $p$ is the number of rises of the Dyck path $\mathcal{D}_\sigma$.

Loosely speaking, $\theta_1$ acts by reversing the maps $\rho_i$, $\theta_2$ acts by reversing the maps $\gamma_j$, and $\theta_3$ acts by applying the $\delta$-procedure to all the "local" maps $\rho_{ij}$.

It is immediately checked that each one of these bijections maps the set $I^*_2$ into itself.

We can also describe the maps $\theta_1$ and $\theta_2$ in algebraic language as follows: given $\sigma \in I^*_2$, for every set $R_i$, we define the reversal map $\alpha_i$ to be the permutation in $S_{2k}$ that fixes all the integers $x \notin R_i$ and reverses the symbols appearing in $R_i$. Similarly, for every set $C_j$, we denote by $\beta_j$ the permutation that fixes all the integers $x \notin C_j$ and reverses the symbols appearing in $C_j$. Define $\alpha$ and $\beta$ to be the compositions of the permutations $\alpha_i$ and $\beta_j$, respectively. The following commutation properties of the reversal maps can be easily verified:

\[ \alpha_i \alpha_h = \alpha_h \alpha_i, \quad \beta_{ij} \beta_l = \beta_l \beta_{ij}, \quad \alpha_i \beta_j = \beta_j \alpha_i. \]

Hence, we do not need to specify the order of such permutations in the compositions $\alpha$ and $\beta$. With this notation, we can readily deduce that

\[ \theta_1(\sigma) = \alpha \sigma \alpha, \quad (16) \]
The Eulerian distribution on centrosymmetric involutions

\[ \theta_2(\sigma) = \beta \sigma \beta. \]  

Finally, we define the bijection \( \theta \) to be the composition

\[ \theta = \theta_3 \circ \theta_2 \circ \theta_1. \]

We are now in position to state Strehl’s theorem:

**Theorem 16** The bijection \( \theta \) maps involutions in \( I_{2k}^* \) with \( t \) ascents into involutions with \( 2k - 2 - t \) ascents.

**Proof:** First of all, a given ascent of \( \sigma \) at position \( x \in R_i \) (respectively \( x \in C_j \)) will be called

- **small ascent** if \( x + 1 \in R_i \) (resp. \( x + 1 \in C_j \)) and there exists \( h \) such that \( \sigma(x), \sigma(x + 1) \in C_h \) (resp. \( \sigma(x), \sigma(x + 1) \in R_h \)).
- **large ascent**, otherwise.

The notion of small descent and large descent are defined analogously.

The maps \( \theta_1, \theta_2 \) and \( \theta_3 \) act on the ascents of \( \sigma \) as follows:

\[ [\theta_1] \]

- If \( R_i = \{ z, z + 1, \ldots, z + r_i - 1 \} \) and \( z + x \) is an ascent (descent) of \( \rho_i^\sigma \), then \( z + r_i - 2 - x \) is a descent (ascent) in \( \theta_1(\sigma) \).
- If \( y \in C_j \) is a large ascent (descent) in \( \gamma_j^\sigma \), then \( y \) is a large ascent (descent) in \( \theta_1(\sigma) \).
- If \( y \in C_j \) is a small ascent (descent) in \( \gamma_j^\sigma \), then \( y \) is a small descent (ascent) in \( \theta_1(\sigma) \);

\[ [\theta_2] \]

- If \( C_j = \{ z, z + 1, \ldots, z + c_j - 1 \} \) and \( z + x \) is an ascent (descent) of \( \gamma_j^\sigma \), then \( z + r_j - 2 - x \) is a descent (ascent) in \( \theta_2(\sigma) \).
- If \( y \in R_i \) is a large ascent (descent) in \( \rho_i^\sigma \), then \( y \) is a large ascent (descent) in \( \theta_2(\sigma) \).
- If \( y \in R_i \) is a small ascent (descent) in \( \rho_i^\sigma \), then \( y \) is a small descent (ascent) in \( \theta_2(\sigma) \);

\[ [\theta_3] \]

- Large ascents and descents of \( \rho_i^\sigma \) and \( \gamma_j^\sigma \) remain unaffected by the map \( \theta_3 \).
- The properties of the Robinson–Schensted algorithm imply that, if \( x \in R_i \) is a small ascent (descent) in \( \rho_i^\sigma \), then \( x \) is a small descent (ascent) in \( \theta_3(\sigma) \).
- Similarly, if \( y \in C_j \) is a small ascent (descent) in \( \gamma_j^\sigma \), then \( y \) is a small descent (ascent) in \( \theta_3(\sigma) \).

Combining now the previous remarks, we deduce that:
We now switch to the centrosymmetric case. The following properties can be readily verified:

- If \( R_i = \{z, z + 1, \ldots, z + r_i - 1\} \) and \( z + x \) is an ascent (descent) of \( \rho^\sigma_i \), then \( z + r_i - 2 - x \) is a descent (ascent) in \( \theta(\sigma) \).

- If \( C_j = \{z, z + 1, \ldots, z + c_j - 1\} \) and \( z + x \) is an ascent (descent) of \( \gamma^\sigma_j \), then \( z + r_j - 2 - x \) is a descent (ascent) in \( \theta(\sigma) \).

- Ascents and descents of \( \sigma \) that are not ascents or descents of any \( \rho^\sigma_i \) or \( \gamma^\sigma_j \) remain unaffected by the map \( \theta \).

In conclusion, consider an involution \( \sigma \in I_{2k}^\pi \) with \( d \) ascents. Observe that \( p - 1 \) of these ascents correspond to positions \( x \) such that \( x \in C_j \) and \( x + 1 \in R_{j+1} \) and are unaffected by \( \theta \). Similarly, the \( p \) descents corresponding to positions \( y \) such that \( y \in R_i \) and \( y + 1 \in C_i \) remain unchanged. We now focus on the remaining \((2k - 1) - (2p - 1) = 2k - 2p\) positions. The involution \( \sigma \) has \( d - (p - 1) \) ascents within these positions, and hence \((2k - 2p) - (d - (p - 1)) = 2k - p - d - 1\) descents. Previous argumentations show that these descents are transformed into ascents of \( \theta(\sigma) \) in suitable positions. This implies that the involution \( \theta(\sigma) \) has

\[
(2k - p - d - 1) + (p - 1) = 2k - d - 2
\]

ascents, as required.

For example, if \( \sigma \) is the involution in \( I_{10}^\pi \) of the previous example, then:

\[
\theta_1(\sigma) = \begin{pmatrix}
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16
\end{pmatrix}
\]

\[
\pi = \theta_2(\theta_1(\sigma)) = \begin{pmatrix}
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16
\end{pmatrix}
\]

Then, we have:

- \( R^\pi_{1,1} = \{3\} \)
- \( R^\pi_{1,2} = \{1, 2, 4\} \)
- \( R^\pi_{2,2} = \{7\} \)
- \( R^\pi_{2,4} = \{6\} \)
- \( R^\pi_{3,3} = \{12\} \)
- \( R^\pi_{4,4} = \{14\} \)

- \( C^\pi_{1,1} = \{5\} \)
- \( C^\pi_{1,2} = \{8, 9, 10\} \)
- \( C^\pi_{2,2} = \{11\} \)
- \( C^\pi_{2,4} = \{15\} \)
- \( C^\pi_{3,3} = \{13\} \)
- \( C^\pi_{4,4} = \{16\} \)

The map \( \theta_3 \) leaves unchanged every \( R_{ij} \) except \( R_{1,2} \):

\[
\theta(\sigma) = \begin{pmatrix}
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16
\end{pmatrix}
\]

Observe that, since \( \sigma \) has 7 ascents, then \( \theta(\sigma) \) has \( 16 - 2 - 7 = 7 \) ascents, as expected.

We now switch to the centrosymmetric case. The following properties can be readily verified:

**Proposition 17** If \( \sigma \) is a centrosymmetric involution in \( I_{2k}^\pi \), then:

- For every \( 1 \leq i \leq p \), if \( R_i = \{x_1, \ldots, x_r_i\} \), then \( C_{p+1-i}^\pi = \{2k + 1 - x_r_i, \ldots, 2k + 1 - x_1\} \) and, hence, \( c_{p+1-i} = r_i \).

- For every \( 1 \leq i, j \leq p \), if \( R_{ij} = \{x_1, \ldots, x_h\} \), then \( C_{p+1-i,p+1-j}^\pi = \{2k+1-x_h, \ldots, 2k+1-x_1\} \).
The Eulerian distribution on centrosymmetric involutions

- the Dyck path associated with \( \sigma \) is symmetric.

The maps \( \theta_2 \circ \theta_1 \) and \( \theta_3 \) preserve centrosymmetry. In fact:

**Lemma 18** If \( \sigma \in I^*_{2k} \) is centrosymmetric, then \( (\theta_2 \circ \theta_1)(\sigma) \) is centrosymmetric.

**Proof:** Consider a centrosymmetric element \( \sigma \in I^*_{2k} \). Proposition [17] implies that the reversal maps \( \alpha_i \) and \( \beta_j \) associated with \( \sigma \) are related as follows:

\[
\psi \beta_j \psi = \alpha_{p+1-j},
\]

where \( \psi \in S_n \) is defined by \( \psi(i) = n + 1 - i \), and hence

\[
\psi \beta \psi = \alpha.
\]

Then, recalling Identities (16) and (17), we have:

\[
\psi((\theta_2 \circ \theta_1)(\sigma))\psi = \psi \beta \alpha \sigma \alpha \beta \psi =
\]

\[
= (\psi \beta \psi)(\psi \alpha \psi)(\psi \sigma \psi)(\psi \alpha \psi)(\psi \beta \psi) =
\]

\[
\alpha \beta \sigma \alpha \beta = (\theta_2 \circ \theta_1)(\sigma).
\]

Hence, the permutation \( (\theta_2 \circ \theta_1)(\sigma) \) is centrosymmetric. \( \square \)

**Lemma 19** If \( \sigma \in I^*_{2k} \) is centrosymmetric, then \( \theta_3(\sigma) \) is centrosymmetric.

**Proof:** Note that the map \( \theta_3 \) consist in applying the transposition map \( \delta \) defined above to each subset \( R_{ij} \), and adjusting the entries in the corresponding \( C_{ij} \) in order to get an involution. We denote by \( \delta_{ij} \) the transposition map \( \delta \) referred to the set \( R_{ij} \), and by \( \hat{\delta}_{ij} \) the unique permutation in \( S_{2k} \) such that

\[
\delta_{ij}(\sigma) = \hat{\delta}_{ij} \sigma.
\]

Clearly, the permutation \( \hat{\delta}_{ij} \) fixes all the elements of the interval \( [2k] \) belonging neither to \( R_{ij} \) nor to \( C_{ij} \). We denote by \( \delta \) the composition of such permutations (we do not need to specify the order in the composition, since the permutations \( \hat{\delta}_{ij} \) commute). We have:

\[
\theta_3(\sigma) = \hat{\delta} \sigma.
\]

Let now \( \sigma \) be a centrosymmetric element of \( I^*_{2k} \). Then

\[
\psi \theta_3(\sigma) \psi = \psi \hat{\delta} \sigma \psi =
\]

\[
= (\psi \hat{\delta} \psi)(\psi \sigma \psi) = (\psi \hat{\delta} \psi) \sigma.
\]

Since \( \sigma \) is centrosymmetric, for every pair \( i, j \) we have

\[
\psi \hat{\delta}_{ij} \psi = \hat{\delta}_{p+1-j, p+1-i},
\]
namely, the conjugate with respect to $\psi$ of the transposition map on $R_{ij}$ is the transposition map on $R_{p+1-j,p+1-i}$. Hence, since the permutations $\hat{\delta}_{ij}$ commute, we have

$$\psi \hat{\delta} \psi = \hat{\delta}.$$ 

This yields the assertion.

These two lemmas immediately imply the following theorem:

**Theorem 20** The map $\theta$ preserves centrosymmetry.

As a consequence, we have:

**Theorem 21** For every positive integer $k$, we have:

$$s^*_{2k,d} = s^*_{2k,2k-d}.$$ 

For example, consider the centrosymmetric fixed point free involution

$$\sigma = \left( \begin{array}{cccccccccccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16 & 17 & 18 \\ 6 & 10 & 5 & 11 & 3 & 1 & 12 & 15 & 17 & 2 & 4 & 7 & 18 & 16 & 8 & 14 & 9 & 13 \end{array} \right)$$

with 10 ascents. Then,

$$\theta_1(\sigma) = \left( \begin{array}{cccccccccccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16 & 17 & 18 \\ 11 & 5 & 10 & 6 & 2 & 4 & 17 & 15 & 12 & 3 & 1 & 9 & 16 & 18 & 13 & 7 & 14 \end{array} \right),$$

$$(\theta_2 \circ \theta_1)(\sigma) = \left( \begin{array}{cccccccccccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16 & 17 & 18 \\ 11 & 6 & 12 & 5 & 4 & 2 & 16 & 18 & 10 & 9 & 1 & 3 & 17 & 15 & 14 & 7 & 13 & 8 \end{array} \right),$$

$$\theta(\sigma) = \left( \begin{array}{cccccccccccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16 & 17 & 18 \\ 12 & 5 & 11 & 6 & 2 & 4 & 18 & 16 & 10 & 9 & 3 & 1 & 15 & 17 & 13 & 8 & 14 & 7 \end{array} \right),$$

that is centrosymmetric with $18 - 2 - 10 = 6$ ascents.

**Acknowledgements**

We thank Volker Strehl who helpfully sent us the manuscript of his unpublished paper and gave us, kind as ever, the permission to include his result with proof in our paper. We also thank the anonymous referee for providing many constructive comments, and the managing editor for the genuine interest devoted to the improvement of the present paper.
